Time prevents my paying a well deserved tribute to the men who in the early days, and at times under discouraging conditions, built up these institutions and labored for the best interests of their patients.

Patients are received into the three asylums only on transfer from the three hospitals, to which they are committed by the Probate Court or admitted on voluntary application.

Training schools for nurses were opened in the state hospitals in 1889, the first of any such schools in the state requiring a two year course and affiliation the third year with a general hospital. These are accredited schools.

During the biennial period ending in 1900, 1,600 patients were admitted to the state hospitals, which was 45 per 100,000 for each year. In 1920 the admissions for the previous two years were 2,800, or 55.4 per 100,000 for each year. For the two years ending in 1930, 3,000 patients were admitted, or 58.5 per 100,000 for each year. This shows an increase in the number of admissions to the state hospitals in the past ten years.

The number present in institutions has increased from 3,364 in 1900 to 7,439 in 1928 and there will be in all probability a continuous increase in the number to be cared for in institutions, necessitating constantly increasing accommodations.

STERILIZATION

Some twenty-five states have a sterilization law. California has sterilized some 7,000 insane patients. Minnesota has gone as far as the law will permit. Some changes could be made to permit an increase in such cases. The feeble minded are unmoral, not immoral, and the women of that class may be the victims of unprincipled men taking advantage of their condition; in their case constant supervision only can replace sterilization. California reports a decrease in promiscuity from 75 per cent to 8 per cent after operation.

It has been said that the number we can sterilize is only a drop in the bucket compared with the total number of mental defectives. If a few of such patients as migrated to Minnesota in 1856 had been sterilized or kept under constant supervision, there would not be now some 500 of their descendants to be cared for by the state or to augment the criminal class.

The members of the senior class of the University Medical School are now serving internships in the state hospitals. I think it is the consensus of opinion that a psychopathic hospital should be established at the University.

THYMOPHYSIN NOT ACCEPTABLE FOR N.N.R.

The Council on Pharmacy and Chemistry reports that Thymophysin is stated to be a preparation of posterior pituitary and thymus, manufactured by Fritz-Pezoldt of Vienna and is marketed in this country by the American Bio-Chemical Laboratories, Inc. Because the claims for its action were inadequate, it was necessary to subject Thymophysin to examination by accurate pharmacologic methods to see whether the claims made for it are justified or whether it might not be merely a weak pituitary extract. This study was made by Prof. Erwin E. Nelson of the Department of Pharmacology at the University of Michigan. He studied the action of Thymophysin as compared with pituitary and again the action of thymus in connection with pituitary. Nelson concluded that there is no unequivocal evidence that either oxytoxic or pressor activities of pituitary are altered by the simultaneous administration of thymus; that experimentally no difference could be found in the oxytoxic, or pressor activities of pituitary alone as compared with pituitary plus thymus; and that Thymophysin ampules contained only about 30 per cent of the strength claimed. The Council declared Thymophysin unacceptable for inclusion in New and Non-official Remedies, since it is an unscientific preparation marketed under false claims as to its essential action, as to its strength, and as to its safety for mother and child. (Jour. A. M. A., March 14, 1931, p. 860.)

SCAR-POX, AN ALLEGED CURE FOR SMALLPOX AND SCARLET FEVER

State and local health officials from Michigan to California have received a form-letter coming from the "White Laboratories" of Chicago, offering to send, on request, a free trial treatment of "Scar-Pox." Among the claims made for Scar-Pox were these: "Scar-Pox, the new and guaranteed remedy for scarlet fever or smallpox"; "Scar-Pox is the tested remedy for the cure of either dread disease, scarlet fever or smallpox"; "It is a vegetable compound, absolutely pure"; "It is guaranteed by the makers to absolutely cure either scarlet fever or smallpox in three days when used as directed." Health officials who received a sample bottle of Scar-Pox were informed that a further supply could be obtained at $15 per bottle. The A. M. A. Chemical Laboratory analyzed "Scar-Pox" and concluded that it was essentially a solution of commercial cream of tartar (about 0.6 Gm. in 100 c.c.). One of the most astounding features of modern civilization is the fact, verified daily, that any person, however ignorant of medicine or pharmacy, cut put up the most fantastically worthless mixtures and sell them as "cures" for some of the most serious diseases known, and there is no legal machinery for stopping it—unless the exploiter is so crude as to violate either the national Food and Drugs Act or the postal laws against fraud. (Jour. A. M. A., March 21, 1931, p. 883.)

CASE REPORTS

TREATMENT OF ADDISON'S DISEASE BY THE CORTICAL HORMONE OF SWINGLE AND PFIFFNER*

REPORT OF CASE

ARTHUR R. KINTNER, M.D.
and
ROSS M. LYMBURNER, M.D.
Fellows in Medicine, The Mayo Foundation
Rochester, Minnesota

The cortical hormone prepared by Swingle and Pfiffner has been used at The Mayo Clinic on the medical service of Dr. L. G. Rowntree in the treatment of five patients with Addison's disease. The first, second and third cases were reported in *Proceedings of the Staff Meetings of The Mayo Clinic,* the fourth case is included in the series of cases reported by Dr. Rowntree at the recent meeting of the American Chemical Society, and the fifth is the subject of this report.

A housewife, aged thirty-six years, presented herself at the clinic for the first time April 14, 1928, because of symptoms of palpitation, dyspnea, weakness and nervousness of two years' duration; the symptoms had become progressively worse. A brownish pigmentation of the skin, typical of Addison's disease, had been present for about a year. Within the year numerous black freckles had appeared over the face, back and hands. The mucous membranes of the cheeks and gums were mottled with a bluish-brown discoloration. The skin was moist, smooth, of fine texture, and closely fitting. Although there had been a loss of 24 pounds in weight, it was not evident to the examiner. The patient had been unable to work for two weeks. The systolic blood pressure was 110 and the diastolic was 73 in millimeters of mercury.

The patient was admitted to hospital and was given the Muirhead treatment. This consisted of epinephrine, 3 minims of a 1:1000 solution hypodermically three times a day, 6 minims by rectum two times a day in 2 ounces of physiologic sodium chloride solution, and desiccated suprarenal cortex, 3 grains three times a day with meals. The rectal administration of epinephrine was discontinued on the fifth day on account of tenesmus. The patient's condition had improved greatly. She felt stronger, her appetite increased, she was less nervous and had gained 2.75 pounds in weight. There was no appreciable change in pigmentation. The blood pressure remained at about the same level. After thirteen days she was dismissed with the advice to continue the treatment at home.

In the course of the next fifteen months the patient returned twice for examination. She had followed treatment faithfully, and each time there was evidence of improvement, as manifested by increased strength and endurance. On her second return to the clinic she reported that she had been able to do light housework without undue fatigue. However, she had lost 7 pounds in weight and there was no change in blood pressure.

On the patient's fourth admission, September 1, 1930, she gave the following additional history. In the previous January she had contracted a cold, which had persisted for several weeks. With the onset of this illness nausea developed and she vomited for about three weeks. She was confined to bed for two months, and improvement had been exceedingly slow. During this illness she had been unable to administer her own treatment, and as a result had discontinued it entirely. She appeared considerably older than on her visit nine months previously. She was markedly depressed, extremely weak and exhausted, and dyspneic on the slightest exertion or excitement. Because of weakness a general examination could not be completed at one time. There was little, if any, change in pigmentation. She had lost 12 pounds in weight. The systolic blood pressure was 102 and the diastolic 64.

The patient was in the hospital for seven days. The first four days she did not receive treatment. During this time metabolic studies were carried out. On the morning of the fifth day, treatment with the cortical hormone of Swingle and Pfiffner was begun. The first and second day of treatment 7.5 c.c. was given intravenously, three times a day, and on the third day two doses of 7.5 c.c. each were given. There was no untoward effect from these injections.

The morning treatment was begun, the patient was in a state of complete exhaustion and mental depression. Anorexia was marked and she vomited her morning meal. That evening there was little, if any, change in her condition. The following day progressive improvement was noted. Her strength had increased, depression was less evident and she had regained her appetite. The morning of the third day of treatment there was no doubt that a complete change had taken place. There was a general feeling of well-being and a remarkable increase in strength and endurance. After her morning bath and a brisk walk along the corridor she had no feeling of dyspnea or exhaustion. She volunteered the information that she had never felt better in her life, and was positive that she could return unaccompanied to her home about 200 miles distant. Within a period of forty-eight hours this patient had undergone a change such as she had not experienced with any other form of treatment. To evaluate the continued effect of treatment we were desirous of observing her for a longer period of time. However, circumstances were such that she was obliged to return home. A letter from her twenty-two days later stated that the trip home was very hard, but at the time of writing she was feeling well and working every day.

---

*Work done in the Division of Medicine, The Mayo Clinic. Submitted for publication November 1, 1930.

COMMENT

The results in this case, and those in other cases in which the cortical hormone of Swingle and Pfiffner has been used, make it appear that progress has been made in the control of the crises of Addison's disease.

FOREIGN BODY (NEEDLE) IN THE ESOPHAGUS

REPORT OF A CASE*

Porter P. Vinson, M.D.
Rochester, Minnesota

If a straight slender pointed foreign body is swallowed and gains entrance into the esophagus it usually passes into the stomach. Frequently, foreign bodies of this type such as needles, straight pins and fish bones become fixed in some portion of the pharynx and are easily removed. The rarity of the presence of a foreign body of this character in the esophagus is the reason for reporting the following case:

A woman, aged seventy years, came to The Mayo Clinic for examination February 6, 1931. Two weeks previously a sticking pain had developed in her throat while she was eating an apple. The fruit had been taken from a bowl that contained needles and pins and she concluded that one of these had stuck into the apple and because of artificial dentures, had not been detected until it lodged in her throat. Examination at her home failed to reveal any evidence of foreign body in the pharynx and it was thought that her symptoms were probably nervous in origin. The sensation gradually became more pronounced, although she continued to eat solid food.

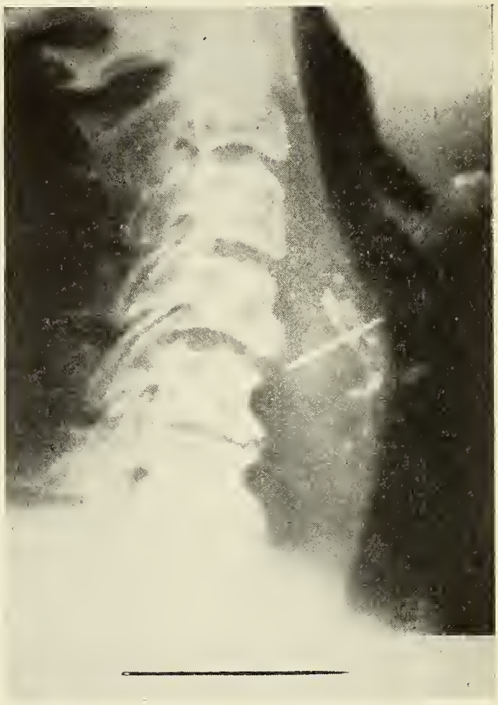

Fig. 1 *(Above).* Foreign body in the upper part of the esophagus.
Fig. 2 *(Below).* Foreign body removed from the esophagus.

General examination at the clinic did not reveal anything abnormal in the pharynx, but roentgenoscopic examination revealed a foreign body in the upper portion of the esophagus (Fig. 1). On esophagoscopic examination, there was evidence of marked inflammatory reaction just beyond the esophageal opening and in this mass of granulation tissue a needle was identified and removed (Fig. 2). Four days later, the patient was apparently perfectly well and was permitted to return home.

PRESIDENT'S LETTER

HOW does the medical profession actually stand in the estimate of the intelligent, unprejudiced layman who is not in immediate need of a physician's services?

It is not always easy to tell. The only voluble expressions come usually from the charlatan who would like to practise healing with no more than an almanac preparation and is balked in his noble desire. These are opinions of no more consequence to intelligent laymen than they are to physicians.

Does the medical profession still hold the exalted position in men's minds that it held in the days after Lister and Koch and Osler and the popular heroes of bacteriology had set it upon the tracks of its greatest developments? Or, has the inevitable antagonism and resistance of the profession to modern mass movements and machine methods subtly reduced it from its high place?

Some of us fear that this last may be the case, the doctor being at present unfortunately between the proverbial devil and the deep blue sea. In this position he may fight the socialization of medicine and risk appearing before the public in an unfortunate light. He may, in preference, cede everything to the bureaucratic tendencies of the times and surrender the most precious ideals and obligations of his profession, to the infinite hurt of both himself and the public.

These are dark thoughts. They occur to every physician upon whom falls the obligation of leadership in his profession.

It is therefore with a distinct sense of gratitude and pride and relief, too, that such a physician comes upon certain important paragraphs in the most comprehensive review of modern Americans and their pre-occupations ever assembled, Mark Sullivan's "Our Times."

Mark Sullivan is an intelligent layman as regards medical achievements but with the newspaper man's keen sense for evaluation and essential accomplishments. He, of all men, is in a position to know how Americans really feel and what their real interest is.

I am quoting herein the Sullivan paragraphs on medicine, lest by chance you may have missed this important lay estimate of modern medical usefulness.

"At the beginning of 1900," says Mr. Sullivan, "it had not yet been proved that yellow fever is transmitted by a mosquito, typhus by a louse, bubonic plague by a flea. Gorgas had not yet demonstrated that mosquitoes may be eliminated from any portion of the earth's surface, and man's only weapon against malaria was quinine. Neither these facts nor the fundamental fact underlying them was known; these plagues were uncontrollable except by the expedient of isolation as they had been since the beginning of history. It was not known that typhoid and cholera come from germs in unclean water and milk; these diseases were still the scourges they always had been. Insulin for diabetes, vaccination against typhoid, emetin for dysentery, adrenalin—all were still unknown. Antitoxin for diphtheria and X-ray were just coming into use. Ehrlich had not yet made those 606 experiments that resulted in the remedy for syphilis. Radium had not yet been used in the treatment of cancer. All these and many other advances in medicine, surgery and sanitation came between 1900 and 1925. They effected a six years' postponement of death and that was but one enrichment of many."

Stupendous accomplishments, these! More important by far than some other showy advances of the early part of the century, flying for instance and wireless communication. And they are only the foundation of greater accomplishments to come.

Sullivan's dramatic recital of the glories of modern medicine should hearten us all. They should strengthen us in our conviction that there is nothing more important in the world, not merely to Medicine itself, but to every living man and woman and child, than the preservation and protection of medicine against traitorous swamp lights of social organization and political meddling.

The medical profession is going through an economic crisis that is apparent now to everybody. In spite of it and of the serious dislocations of the Great War the great recital might go on. It is being expanded every day.

Sullivan recognizes it. Let not the doctor himself weaken and fall behind!

L. Sogge

OUR STATE MEETING

Of the numerous medical meetings we have the opportunity of attending, the county medical societies which are the component units of the state medical association are, after all, the most important.

Just as the local county society reflects the various scientific and economic activities of the county, the state organization reflects the state activities. Our state organization gives its age as seventy-eight. What other medical society in the state can claim seniority? And the state organization is in all human probability a perpetual organization watching the rise and fall, the birth and death of other medical societies.

Just as it is the duty and privilege of each physician to join and take active part in his county society, making his influence felt in the smaller circle, it is also incumbent upon him to take part in a small or large way whenever possible in state medical activities. How can one better be active than by attending the State Meeting in Minneapolis?

The program this year promises to be a larger one than in past years with four sections instead of one or two, the time saved to be devoted to clinics, which after all are more educational than listening to addresses.

Our April issue contained the scientific program of the meeting. Additional news is contained elsewhere in this issue. Why not plan to attend?

A MOTHER INDIA OF MEDICINE

Harpers came out recently with an article* in arraignment of present-day practices in the medical profession. After reading the article, one is forced to admit, "Yes, all these things exist." Tonsils are unnecessarily removed, fees are split, surgeons operate unnecessarily for the fee, unqualified specialists do exist. But does this article correctly represent the present day status of medical practice. No!—emphatically no! The author has selected practices which are not new, which have doubtless existed for centuries, which exist today and which will be fought by the majority of the medical profession a hundred years from now just as they are being fought by the right minded members of the profession today.

The fundamental problem is one of honesty. Until medical licenses can be restricted to those who are inherently honest, these vices cannot be excluded from medical practice.

Certain constructive efforts have been made in recent years to correct the abuses maintained. Medical schools and state examining boards make some effort to weed out morally delinquent individuals with probably little success. The American College of Surgeons was founded in an effort to separate the surgical sheep from the goats. Have the goats been excluded? The task was well nigh impossible to begin with although much good has been accomplished.

---

*Bromley, Dorothy Dunbar: Specialists at Large, Harpers, Feb., 1931.

Perhaps the establishment of standards for Class A hospitals has done more for the betterment of medical practice than any other one regulation. Staff meetings, a trained pathologist and the frank discussion of operative specimens and autopsy findings, combined with a conscientious and fearless executive committee of the staff should serve as a definite check of the surgeon and internist as well. Then, too, the various societies devoted to the specialties make an effort to establish standards conducive to honest practice.

After all is said and done, the practice of medicine affords many opportunities for dishonest practices. No amount of regulations can make an honest man out of one who is inherently dishonest. We hold that the rank and file of the profession is innately honest and trying to serve the public well. Articles such as the one mentioned only serve to give a biased view of the present day situation and are destructive instead of constructive.

OUR POLICY

We hear from time to time criticisms of the editorial policy of Minnesota Medicine. A suggestion was recently made that our policy be altered to admit more discussion of the economic phases of medicine.

It might be well to define what we consider our policy. During its brief existence, the journal has been operated with the idea that the main function of a state journal and Minnesota Medicine in particular should be to make physicians better physicians. If we can share in accomplishing this objective, the existence of the journal is justified. To accomplish that end, we attempt to publish articles of scientific value. Our advertisements are selected from the same viewpoint. We believe that if physicians do their job well, they have little to fear from encroachments on the part of the cultists and irregulars.

The subject of medical economics is not new. Individual physicians have always been concerned with economic problems of one kind or another and always will. Individually and collectively we are and should be interested in the various economic trends affecting medical practice. One of the functions of a state journal is to give expression to views on the various phases of the subject. No article has ever been barred from our pages because it dealt with an economic phase of medicine. A perusal of back numbers of the journal will show that economic subjects are by no means conspicuous by their absence. Contributions on this phase of practice are welcomed.

It is our hope, however, that Minnesota Medicine will never allow medical economics to outweigh the scientific side of practice in its pages. When a physician becomes more interested in financial returns than in scientific attainment, he has lost in his professional ideals. So with a professional journal.

NORTHWEST REGIONAL MEDICAL CONFERENCE

Few of our members are acquainted with the purposes or even the existence of the Northwest Regional Medical Conference.

Realizing the desirability of joint action in policies advocated by the various state medical associations, it was thought advisable to have periodic conferences of the officers of state medical associations in the Northwest. The first conference in this part of the country was called by Dr. W. F. Braasch of Rochester in 1927, and yearly conferences have been held since that year, the last having been held at Saint Paul, February 8, 1931.

The conference was designed as an informal clearing house for new ideas and joint problems confronting the officers of the state medical associations in this region. Membership includes Montana, North and South Dakota, Wisconsin, Iowa, Nebraska and Minnesota. Representatives from these states, with the exception of Montana and Nebraska, met at the Saint Paul Hotel on February 8, for an all day session.

State lines are no barriers when it comes to medical problems, whether they take the form of quackery or changes in popular attitudes. Whatever was a potential menace in Wisconsin yesterday may be a problem in Minnesota today or in Iowa tomorrow.

This Regional Conference, is, therefore, an invaluable aid to leaders of the profession in the Northwest. It prepares them in advance for problems they will all have to meet. It enables them to assume a uniform attitude towards local and national policies. Incidentally, these conferences are important in the education of incoming presidents for their tasks. The 1931 meeting in Saint Paul set a high mark in medical statesmanship towards which its participating members can work during this year.

Next year the A. M. A. delegates from these same states will also be invited to attend the conference which will be held in the Twin Cities, this being the most central to the states involved.

For the ensuing year, Dr. Otho Fiedler, president-elect of the Wisconsin State Medical Association, was elected president; Mr. Vernon D. Blank, managing director of the Iowa State Medical Association, secretary.

E. A. M.

COMMUNICATION

BEWARE THIS SOLICITOR

St. Joseph, Mo., March 30, 1931.

To the Editor:

On February 23, this year, a solicitor victimized a number of physicians in St. Joseph. His plan was to solicit subscriptions to Harpers and other magazines and to offer sets of books as premiums. The subscription blank called for the payment of $9.70 in ninety days. He was supplied with blanks, samples of binding and everything to indicate that he was a bona fide magazine salesman.

After he had secured the signature on the subscription blank, he explained in an indifferent manner that if the subscriber cared to pay cash, or by check, there was a discount of $1.00, and the check could be made payable to "Harper Brothers Publishing Co.," the name printed on the subscription blank. The doctors "fell for it" and the next day he cashed the checks at a local bank and departed. He used the name T. T. McLean while here but has also used the name Leroy Dale.

Correspondence with the National Publishers Association, 15 West 37th St., New York, indicates that this person has been defrauding physicians in the Middle West for several months.

E. J. Goodwin, M.D.

"When a drug really possesses the virtues attributed to it, and is an effective remedy for disease, its survival into modern times is quite natural, but the fact that many quite fantastic remedies have been carried on almost to our own days, is definite proof of the slavish copying of the works of one writer to another in a continuous line that originated many centuries ago on the banks of the Nile."—From Magician and Leech. —Warren R. Dawson.

OBITUARY

BYRON W. PARROTT

1869-1931

The death of Dr. Byron W. Parrott on April 2, 1931, at his home in Long Prairie, proved a shock to the people of Long Prairie and the vicinity where he had practiced his profession since 1899. A brief illness from pneumonia preceded his demise.

Dr. Parrott was educated in the public schools of Faribault, Minnesota, and received his medical degree at the University of Minnesota in 1897, taking his internship at the City and County Hospital in St. Paul.

During the World War Dr. Parrott served as Captain in the Medical Corps of the United States Army and resumed practice following the armistice.

He was of a kindly and sympathetic nature and these attributes held the friendship of all who knew him.

Dr. Parrott is survived by his widow, and one son, Dr. Earl C. Parrott of South Milwaukee, Wisconsin.

BOVININE AND NEOBOVININE NOT ACCEPTABLE FOR N.N.R.

The Council on Pharmacy and Chemistry reports that Bovinine and Neobovinine are marketed by the Bovinine Company of New York and Chicago. In 1909 the Council reported that while Bovinine was advertised as a "condensed beef juice prepared by a cold process," it was not meat juice but a mixture of alcohol, glycerin, added sodium chloride, and apparently some form of defibrinated blood and that the product was marketed with unwarranted claims. In 1914 the Council reported that the unwarranted claims were, for the greater part, still made, and also that the conclusions of the first report were fully warranted by the experimental evidence. The Council has not given consideration to the product since the report in 1914 was issued. Attention having again been called to Bovinine through the advertising for a similar one, "Neobovinine," which is marketed with it, a referee of the Council reported that for Bovinine the situation remained about the same as when the product was last considered. Neobovinine 20 is stated to be "essentially BOVININE *(Plain)* in which is incorporated the active principle of fresh whole liver." Certainly the combination of Bovinine with a liver extract of undeclared character must be held an unscientific mixture. The case histories are entirely unsatisfactory and report conditions in which it is known that there could not possibly be the results reported. The cases of pernicious anemia are not reported with sufficient data on which to base an opinion. The Council reaffirmed the rejection of Bovinine and declared Neobovinine unacceptable because the information in regard to its composition is inadequate, because the therapeutic claims advanced for it are unwarranted, and because the combination of "Bovinine" with a liver extract of undeclared character is unscientific. (Jour. A. M. A., March 14, 1931, p. 860.)

« A PAGE FORUM OF THE COMMITTEE ON PUBLIC HEALTH EDUCATION »

LET THE COUNTY SOCIETY DO IT!

It is one thing, as every busy physician must feel, to recognize the obvious threat of socialization of medicine in America. It is another to know just what to do about it.

This feeling of helplessness and bewilderment is not very successfully dispelled by much of the discussion on the subject, even by representatives of organized medicine. Mostly these discussions deal at length with unmistakable signs of the times. But by way of conclusion there is usually only a vague, sweeping exhortation to the physician to hurry up and do something.

In this respect, an article by Dr. G. A. Harper, State Health Officer of Wisconsin, published recently in the United States Daily in Washington, D. C., is remarkable. His advice to the profession, quoted below, is definite and practical. Dr. Harper says the county society can carry on the battle in its routine dealings with the rest of the world. In the handling of small, close-at-hand problems involving the relations of the county society to the State Health Department, the social service organizations, the public press, lies the solution of all the large problems of medicine in America. Here and not in some showy general movement is where he would start the intrenchment and defense for the dignified, independent, competitive practice of medicine against well meant but ill-advised social reform.

Dr. Harper says:

"One of the first steps towards the prevention of general socialized medicine would be for each county medical society to select a committee to study the problem in all its aspects—the duties of this committee should be to work out a procedure as to public education, to make contact with public officials and various welfare agencies, to interest itself practically in community problems, particularly relating to health and general welfare. Such committees should bring the entire medical profession in as part of the body politic. They should go out of their way to help solve many of the minor problems that are agitating local governing officials.

"By finding a proper solution to minor problems undoubtedly the larger and more vital problems—so far as the profession is concerned—would be held in abeyance or entirely eliminated.

"The first application of such a procedure should be simple and fundamental and concern itself, probably, with solving the medical care problem for the indigent. Social Agencies should be given aid and assistance. The objectives of the Health Department should be better understood and a plan worked out for closer coöperation. Known scientific procedure should be handled by the County Medical Society but mainly as a community problem which cannot be left wholly, as things are now, to the individual family and the family physician.

"For a century vaccination against small-pox has been known but in its general application little advance has been made. Toxin-antitoxin can be similarly classified. The monetary consideration in dealing with this problem is minor no matter how it is handled when compared to its possible effect in abating the tendency to socialization of medicine. The principle should assuredly be established that the medical profession is to be paid for services rendered. Whatever the sum may be is secondary to the establishment of the fundamental principle in the minds of the governing body and the citizenship as a whole that the medical profession should not be pauperized.

"In view of the fact that it is estimated that 70 per cent of our citizenship does not get the proper medical care at the time it is needed, we must and do admit that something is wrong with the present system. It would not appear, however, that general socialization of medicine is the remedy. Proper organization of the system of medicine that now exists, proper education of the public to the value of medical care at the time it is needed, whether it is preventive or curative medicine, are the logical solutions. Organized medicine must assume the responsibility in these things if it is to maintain its independence. I believe the county units, backed by the State and National Societies, hold the key to the situation."

OF GENERAL INTEREST

Dr. F. R. Huxley is now spending a vacation in Florida.

Dr. Brand O. Leopard has moved from St. Cloud, Minnesota, to Evanston, Illinois—2602 Eastwood Avenue, Apt. F-1.

Dr. Lawrence R. Boies has returned to Minneapolis to limit his practice to Oto-laryngology, after an absence of two years spent in special study at the Harvard Medical School, and as a House Officer at the Massachusetts Eye and Ear Infirmary. He has offices at 1833 Medical Arts Building.

Dr. Leo M. Crafts, of Minneapolis, has been named as a delegate to the International Neurological Congress which meets at Berne, Switzerland, the last of August and the first week of September, 1931. His present plans meditate spending the earlier part of the summer in travel in the British Islands and on the Continent, including comparative clinical observations at Edinburgh, London, Paris and Rome according to his usual custom on previous trips, arriving in Switzerland at the end of the season in time for the sessions of the Congress.

Dr. Crafts is the author of the first comprehensive textbook ever published on "Epidemic Encephalitis," designated by the American Medical Editors and Authors Association as standard text on this subject, and has recently been awarded their diploma certificate of membership "in recognition of his contributions to medical knowledge." The Research Council of the National Academy of Science also credits him with four separate contributions to scientific knowledge through original research in "Family Periodic Paralysis," "The Early Recognition of Multiple Sclerosis," "An Original Test for the Pathologic Great Toe Sign," and "The Iris Sign in Locomotor Ataxia."

TUBERCULOSIS PREVENTION CAMPAIGN

Dr. F. E. Harrington, Minneapolis commissioner of health, will direct the fourth annual tuberculosis prevention campaign which will be conducted in Minneapolis April 19 to May 1. The campaign, sponsored here by the Hennepin County Tuberculosis Association, is part of a nationwide educational program carried out through 1,400 tuberculosis associations, to focus the attention of the public on the importance of early diagnosis. "Tuberculosis—The Foe of Youth," is the slogan of the campaign this year which will place special emphasis on the tuberculosis of early maturity.

CANCER CLINICS

Dr. Joseph Colt Bloodgood of Johns Hopkins University, Baltimore, will conduct a morning and afternoon clinic, showing bone tumors and other new growths, at a meeting of the Radiological Section of the Wisconsin State Medical Society, Schroeder Hotel, Milwaukee, May 27, 28, and 29.

Presentation of cases will be by lantern slides and include the following material: (1) Short clinical history (diagnosis omitted), (2) Photographs, (3) Radiographs, (4) Microphotographs, (5) Serial radiographs of cases treated by radiation.

Members of the Minnesota State Medical Society are cordially invited to attend this meeting and show their interesting bone tumor cases at the clinics. Send us a list of the cases you desire to show.

Program of meeting, hotel reservation, and other information on request.

Further information may be obtained from Frank W. Mackoy, M.D., Secretary, Sacred Heart Sanitarium, Milwaukee, Wisc.

POST-GRADUATE COURSES, DELIVERED IN THE ENGLISH LANGUAGE IN THE LEADING HOSPITALS OF PARIS (FRANCE)

The Faculty of Medicine of Paris (The Medical School of the University) announces that, during June and July, 1931, a comprehensive series of post-graduate courses will be presented. The enterprise is conducted under the auspices of the Association for the Development of Medical Relations (the "A. D. R. M."), a commission sponsored by the French Government.

The work will be presented in the English language. Clinics, lectures and demonstrations will be conducted in the great hospitals of Paris, on a wide variety of topics, by the most eminent French clinicians. A nominal fee will be charged for each course. Upon the completion of each course, the student who qualifies will receive a certificate covering the work, signed by the professor in charge.

Detailed information may be secured by addressing direct, Professeur E. Hartmann, President, "A. D. R. M.," Faculty of Medicine of Paris, 12, Rue de L'Ecole de Medicine, Paris (6e) or, in the United States, Doctor Frank Smithies, 920 North Michigan Avenue, Chicago, Illinois.

MINNESOTA ALUMNI LECTURE COURSE

The Minnesota Medical Alumni Association organized, and is now giving, a course of lectures to the Senior medical students under the direction of Dr. Sam Solhaug. These lectures are on topics not usually included in the regular school curriculum. They are being given weekly on Friday afternoons at 5:00 o'clock in the Eustis Amphitheatre throughout this spring quarter. The attendance has been very gratifying and if the project meets with general approval it is planned to have the series repeated in the spring and fall hereafter, in order that all Seniors may have the advantage of hearing the speakers.

The course as arranged this spring is as follows: Dr. A. S. Hamilton has already spoken on "Medical Ethics," and Dr. John Hynes on "Art and Experience in Medicine." Dr. P. D. Ward, Superintendent of Miller Hospital, St. Paul, will speak on, "The Relation of

Hospital and Staff Physicians." Dr. W. A. Coventry of Duluth will discuss, "Medical Organizations." "Business Methods in Medicine" will be discussed by Mr. A. G. Stasel, and Dr. N. O. Pearce will present the topic, "Social Service in Relation to Medicine." "Public Health and Civic Aspects of Medicine" will be the subject of a talk by Dr. O. E. Locken of Crookston and Mr. E. J. McGough, Attorney, will talk on "Compensation Insurance." Other subjects may be included in subsequent courses.

NEW AND NON-OFFICIAL REMEDIES

The Council on Pharmacy and Chemistry has accepted the following:

Ciba Company, Inc.
- Nupercaine-Ciba
  - Ampules Buffered Solution of Nupercaine-Ciba, 2 c.c., 1:200
  - Ampules Solution of Nupercaine-Ciba, 5 c.c., 1:1,000
  - Solution of Nupercaine-Ciba, 2%
  - Tablets Nupercaine-Ciba, 50 mg.

Lederle Laboratories, Inc.
- Refined and Concentrated Antipneumococci Serum, Type I-Lederle

Mead Johnson & Co.
- Mead's Powdered Brewer's Yeast

Schieffelin & Co.
- Schieffelin Psyllium Seed

Swan-Myers Company
- Mixed Grass Pollen Extract-Swan-Myers
- Russian Thistle Pollen Extract-Swan-Myers

TRUTH ABOUT MEDICINES

Antipneumococcic Serum, Type 1.—An antipneumococcus serum (New and Non-official Remedies, 1930, p. 351), marketed in packages of one 50 c.c., double-ended vial with apparatus for intravenous injection. The National Drug Co., Philadelphia.

Erysipelas Antistreptococcus Serum.—A specific serum containing the antibodies and antibacterial properties of *Streptococcus erysipelatis.* For therapeutic use against erysipelas it may be of value when administered in adequate doses in the early stages of the disease. Though there is no evidence for the value of nonspecific antistreptococcus serums, there appears to be some evidence for the value of a serum representing the antigenic and antibacterial properties of *Streptococcus erysipelatis.*

Erysipelas Antistreptococcic Serum-Lilly (Concentrated Globulin).—The serum is obtained from horses immunized with strains of hemolytic streptococci obtained from human cases of erysipelas. It is marketed in packages of one syringe containing an average initial theraputic dose. Eli Lilly & Co., Indianapolis.

Richards Psyllium Seed.—A brand of psyllium seed-N. N. R. (New and Non-official Remedies, 1930, p. 311). Richards Pharmacal Co., Inc., New York.

Ointment Scarlet Red Biebrich 8 Per cent.—An ointment composed of scarlet R medicinal Biebrich-N. N. R. (New and Non-official Remedies, 1930, p. 148) 8 per cent in a base consisting of stearin, wool fat and petrolatum. The National Drug Co., Philadelphia.

Typhoid-Paratyphoid A Vaccine.—This product (New and Non-official Remedies, 1930, p. 373) is also marketed in packages of three 1 c.c. vials. The National Drug Co., Philadelphia. (Jour. A. M. A., December 6, 1930, p. 1745.)

Antirabic Vaccine, Semple Method.—An antirabic vaccine (New and Non-official Remedies, 1930, p. 352) prepared according to the general method of David Semple (phenol killed). It is marketed in packages of fourteen vials, each containing 2 c.c.; in packages of fourteen vials, each containing 2 c.c. and a syringe; in packages of fourteen syringes, each containing 2 c.c. Medical Arts Laboratory, Inc., Oklahoma City, Oklahoma.

Diphtheria Toxoid-Squibb.—This product (New and Non-official Remedies, 1930, p. 364) is also marketed in packages of twenty 1 c.c. ampules of diphtheria toxoid and two 1 c.c. ampules of diluted diphtheria toxoid for the reaction test. E. R. Squibb & Sons, New York.

Normal Horse Serum.—This product (New and Non-official Remedies, 1930, p. 340) is also marketed in packages of one 50 c.c. vial. E. R. Squibb & Sons, New York.

Sodium Gold Thiosulphate—Sodii et Aurii Thiosulphas—Gold Sodium Thiosulphate.—The complex salt formed from one molecule of gold thiosulphate and three molecules of sodium thiosulphate, containing approximately 37.4 per cent of gold. The use of sodium and gold thiosulphate in the treatment of lupus erythematosus is considered a distinct advance in the therapy of this condition. The beneficial and often curative action of the drug in a good percentage of cases seems to warrant giving it a definite place in the treatment of a disease for which at present there is no specific remedy. The drug must be used with extreme caution. Dosages at first advocated have been found too great, resulting frequently in severe and even fatal reactions. Even with smaller doses, accidents have occurred.

Gold Sodium Thiosulphate-Abbott.—A brand of sodium gold thiosulphate-N. N. R. It is supplied in ampules containing respectively 0.05 Gm., 0.1 Gm., 0.25 Gm., and 0.5 Gm. Abbott Laboratories, North Chicago, Ill.

Diphtheria Toxin-Antitoxin Mixture (Diphtheria Prophylactic).—This product (New and Non-official Remedies, 1930, p. 356) is also marketed in packages of one hundred and fifty 1 c.c. vials, fifty immunizations. The National Drug Co., Philadelphia.

Diphtheria Toxoid.—This product (Jour. A. M. A., November 15, 1930, p. 1505) is also marketed in packages of ten immunization treatments containing two 1 c.c. vials of diluted diphtheria toxoid for the reaction test and twenty 1 c.c. vials of diphtheria toxoid for treatment; in packages of fifteen immunization treatments containing one 1 c.c. vial of diluted diphtheria toxoid for the reaction test and one 30 c.c. vial of diphtheria toxoid for treatment. Lederle Laboratories, Inc., Pearl River, N. Y.

CONSULTATION BUREAU

Wm. A. O'Brien, M.D., *Director*
Minnesota State Medical Association
11 West Summit Avenue
Saint Paul, Minnesota

1. *Question.*—A boy of three was seen three months ago with an enlarged right tonsil. The left tonsil was twice the size of the right and there was moderate enlargement of the left cervical glands. Tonsillectomy was done and the child not seen again until now. Present condition shows extreme enlargement of all left cervical glands, all separate, the two largest fluctuating. Contents are grayish fluid containing lymphocytes. There is also enlargement of right and left axillary and right and left groin glands. The spleen is not palpable, and there is no enlargement of the right cervicals. Blood erythrocytes 4,200,000; leukocytes 11,200; 65 per cent lymphocytes; hemoglobin 80 per cent. Biopsy report on gland removed does not show malignancy. Tuberculin test was negative. There was also some arthritis and fever. What is your diagnosis, if above is sufficient to make one?

   Answer.—Leukemia should be given first consideration. A careful study of the stained smear might reveal immaturity in the lymphocytes. We note that the count is not greatly elevated but that 65 per cent lymphocytes are present. The reported hemoglobin of 80 per cent is against the diagnosis of leukemia and favors some form of infection with a reaction in the blood especially along the lymphocyte line. This is also suggested by the statement that some arthritis and fever are present. It is a matter of common clinical experience that enlargement of the tonsils may be the first obvious signs of leukemia. You did not state the condition of the mouth. Frequently, infections in children are associated with a form of stomatitis (Vincent's organisms). The blood should be examined at frequent intervals, and if signs of immaturity are constant, a diagnosis of leukemia is justified. Otherwise, some type of general infection with probable portal in the throat is the condition which seems most obvious.

2. *Question.*—Patient, age 49, married, one child living and well. For the past eleven years, the left breast has discharged a clear, serous fluid on pressure. The patient states that if she sleeps on the left side there will be a discharge from the breast. The past year she has noticed a little blood in the discharge and a small lump that comes and goes. I could not find a lump on examination (breast is soft). She states that sometimes it is a little sore to the touch around the nipple. She fears cancer. Would cancer be likely with a condition of such long standing?

   Answer.—The commonest cause of discharge from the nipple, whether clear or bloody, is cystic disease. Very often the bloody discharge is due to a papilloma in the duct. The fact that the mass comes and goes would suggest that a papilloma is present (retention). If a definite mass can be palpated, it is necessary to remove the same for microscopic study. If you cannot palpate a definite mass and your patient continues to worry about cancer, it would be advisable to have her come in when she feels a lump and remove the same for study. Cancer may develop in any type of breast, normal or otherwise. The most important thing to do is to examine all lumps to find out whether they are malignant or not.

3. *Question.*—A single woman, age 22, had an appendectomy done under local anesthesia. The appendix showed moderate inflammation. Convalescence was uneventful, until the seventh day, when she insisted that she was well enough to leave the hospital. Permission was denied, but she was allowed to be up and about on the eighth and ninth days for a little while and experienced no untoward symptoms. The tenth postoperative day, she felt very good and was given permission to go home. She was assisted in her dressing by the nurses, and felt so well that she thought she could carry a small suit case. She was assisted in walking to an automobile, about seventy-five feet away. Just as she was being helped on to the running board, she slumped into the attendant's arms so suddenly that she was almost allowed to fall to the ground. Her face was cyanotic, and she developed involuntary urination and defecation. She was completely unconscious. They carried her back to the hospital, where she was found to be pulseless, breathing very shallowly and rather slowly. Artificial respiration was done for some time and stimulants were injected. We could not get the slightest sign of pulse or hear anything over the cardiac region at this time. There was no history of any previous illness so far as I know with the exception of the attack of appendicitis which necessitated the operation. What are the possible causes of death?

   Answer.—In the absence of an autopsy, no definite opinion can ever be rendered in a case like this. Many of them are classified as heart failure. Acute cardiac dilation is probably unknown. Experiments conducted on animals indicate that the pericardial sac around a normal heart will not allow this condition to take place. Hearts which are chronically dilated as the result of hypertrophy may suddenly fail, but this is not acute dilation. Other causes are pulmonary embolism, cerebral embolism and hemorrhage. Most of the cases of pulmonary embolism develop in individuals who have silent thromboses in the pelvis or femoral veins. The condition is probably brought about through stasis following operative procedures, and may occur after operations on any part of the body. The clot detaches when the patient attempts to move about and sudden death is due to plugging both the branches of the pulmonary artery. The absence of clinical signs of thrombophlebitis would not be against this possibility in your case. The head should always be examined in sudden death as many unsuspected conditions may be found in this region, *e.g.,* in a recent postoperative death a large silent brain tumor was discovered. Older clinicians always taught that an examination of the heart, lungs, and brain is indicated in any sudden death. Toxic changes in the myocardium may cause sudden failure, but this type of cardiac failure is not common except in severe forms of this condition, *e.g.,* diphtheria. In a considerable

(Continued on Page 462)

REPORTS AND ANNOUNCEMENTS OF SOCIETIES

MEDICAL BROADCAST FOR THE MONTH

The Minnesota State Medical Association Morning Health Service

The Minnesota State Medical Association broadcasts weekly at 11:15 o'clock every Wednesday morning over Station WCCO, Minneapolis and St. Paul (810 kilocycles or 370.2 meters).

Speaker: Dr. William A. O'Brien, M.D., Associated Professor of Pathology and Preventive Medicine, Medical School, University of Minnesota.

The program for the month of May will be as follows:

May 6—The Enuresis Problem.
May 13—Spring Tonics.
May 20—Botulism.
May 27—Bone Tumors.

MINNESOTA STATE MEDICAL ASSOCIATION

An important scientific program, amounting, in fact, to a two-day medical short course, will feature the 78th Annual Meeting of the Minnesota State Medical Association scheduled to open Tuesday morning, May 5th, at the Nicollet Hotel in Minneapolis.

This program is to be divided into three parts. The first, to be held in the Nicollet Hotel Ball Room, is a symposium on surgery and obstetrics.

The second, to be held at the University of Minnesota Hospitals, is to take the form of continuous all afternoon clinics in four amphitheaters of the institutions. There will be thirty-two of these clinics in all. One group to be held in amphitheater A will be varied; Group B will be chiefly medical; Group C chiefly pediatric and Group D chiefly surgical. Eight clinics will be held consecutively in each group and no two will be alike. They will have as leaders members of the University of Minnesota Medical School teaching staff and other Minnesota leaders.

A symposium on diagnosis at the Nicollet Wednesday morning constitutes the third important section of the program. The fourth will be a symposium on therapy Wednesday afternoon.

Scientific and commercial exhibits, all intimately related to the program, are to distinguish this meeting. The first scientific talking pictures ever secured for one of these meetings are to be a continuous feature of the exhibit room, which constitutes the entire mezzanine floor of the Hotel. A prize for the best individual exhibit will be presented by the Southern Minnesota Medical Society, following the precedent set by the Society at Duluth last year.

The annual banquet, scheduled for Tuesday at 7 P. M., is the major social event of the two-day session with alumni and fraternity luncheons scheduled for noon each day and a golf tournament at the Midland Country Club Monday afternoon, May 4th, preceding the meeting.

Other pre-program events are the council meeting scheduled for Monday afternoon at 3 P. M. and the House of Delegates meeting in the Nicollet Hotel ball room Monday night at 7:45 P. M.

The Women's Auxiliary of the Association will hold its Annual Meeting as usual in conjunction with the Association meeting.

Any alumni or fraternity groups who wish to hold reunions during the two days of the Minnesota State Medical Association annual meeting, are requested to call Dr. C. J. Arenberg, 1013 Medical Arts Building, Minneapolis, Geneva 6768, for accommodations and dates.

The University of Minnesota Alumni Association and Phi Beta Pi fraternity luncheon are scheduled for Wednesday noon. Accommodations are still available for others during or preceding the meeting.

NORTHERN MINNESOTA MEDICAL ASSOCIATION

The Northern Minnesota Medical Association meeting will be held in Hibbing, Minnesota, Friday and Saturday, September 18 and 19, 1931.

The Program Committee consists of: Dr. W. L. Burnap, Fergus Falls; Dr. Cyril Smith, Duluth; and Dr. O. O. Larson, Detroit Lakes, who is also Secretary.

This Committee will be glad to hear from anyone who wishes to give a paper.

B. S. Adams, M.D.

RICE COUNTY MEDICAL SOCIETY

A meeting of the Rice County Medical Society was held April 3 in the Faribault Clinic rooms. Dr. F. A. Engstrom, Wanamingo, Minn., was elected to membership in this society and also Dr. Laura A. Lane, of Northfield.

Dr. H. E. Michelson, Minneapolis, the principal speaker of the evening, addressed the society on "Dermatology," and gave an excellent presentation worthy of commendation.

C. J. Plonske, *Secretary.*

SCOTT-CARVER COUNTY MEDICAL SOCIETY

A meeting of the Scott-Carver County Medical Society was held at the Broz Hotel of New Prague, March 10, 1931. Dr. Martin H. Nordland of Minneapolis, gave a talk on the "Thyroid Gland" and with lantern slides and motion pictures illustrated his method of pre-operative ligation of the inferior thyroid artery. Through the courtesy of the Petrolagar Laboratories, Mr. F. A. Augustine of Minneapolis presented motion pictures on the following subjects:

"The Anatomy of the Abdominal Wall"
"Hydrocele"
"Appendectomy"
"Colles Fracture"

WOMEN'S AUXILIARY
Minnesota State Medical Association

President—Mrs. S. S. Hesselgrave, St. Paul
Chairman Press and Publicity—Mrs. E. A. Meyerding, St. Paul
Editor—Mrs. A. A. Passer, Olivia

Through the courtesy of the Minnesota Federation of Women's Clubs, the Women's Auxiliary to the state medical society broadcast a Health Program over WCCO, Monday afternoon, March 16. Mrs. S. S. Hesselgrave, state president, was one of the speakers.

WOMAN'S AUXILIARY TO THE AMERICAN MEDICAL ASSOCIATION

Ninth Annual Meeting
Philadelphia, June 8-12, 1931.
Headquarters, Bellevue-Stratford Roof Garden
Registration Hours, daily 9 A. M. to 5 P. M.

All women attending the convention, whether Auxiliary members or not, are invited to participate in this entire program.

All tickets and invitations must be *procured in advance* in the Bellevue Roof Garden. Only programs will be obtainable elsewhere.

The Woman's Auxiliary to the American Medical Association has been placed in charge of all entertainment of women visitors, and began its labors on June 27, 1930, by engaging the whole Roof Garden of the Bellevue-Stratford Hotel for the period of the convention. All women's activities will center in this hotel—registration, meetings, luncheons and supper dance, and all excursions will start from the Broad Street entrance. Invitations and tickets must all be procured in the Roof Garden *in advance,* as nothing but programs will be obtainable elsewhere. Members of the A. M. A. are invited to join all excursions, and should register for them in advance in the Roof Garden. Rooms for State Headquarters have also been reserved in the hotel, and sponsors will be appointed to look after all women registered from their own states. The list of sponsors will be printed in the program. We take this opportunity to thank the management of the Bellevue for their generosity in placing all these facilities at our disposal free of charge. The chairman of the Women's Hotel Committee is Mrs. Frederick S. Baldi, 2117 Porter Street, Philadelphia, who will be glad to make any desired reservations.

The convention will open with a subscription buffet luncheon in honor of all National Auxiliary Presidents from Mrs. Red to Mrs. McGlothlan, immediately followed by three round tables of 35 minutes each, with 10 minute intermissions, each under expert leadership. The subjects will be:

1. Programs for County Auxiliary Meetings.
2. The Technic and Value of a Committee on Public Relations.
3. History and Archives.

These informal gatherings will be a sort of preliminary canter, designed to bring together those interested in special phases of Auxiliary work and give them opportunity to discuss the subject thoroughly during the following days. The National Board dinner and preconvention meeting are scheduled for Monday evening.

A new and, we hope, helpful feature will be a Question and Suggestion Box to which we beg all with good ideas to contribute. This seems the most practical way of finding out what our members want continued, what discarded, and what plans are indicated for the future.

The regular business sessions will be held on Tuesday and Wednesday mornings. National Chairmen will be allowed 10 minutes for their reports, State Presidents 3 minutes. Reports to be printed may be as long as desired (in reason), but let no one reporting on the floor imagine these limits an idle jest. Nor will the hours announced on the program be found to mean "about." Have your watches cleaned and regulated, and practice your wrist drill before leaving home. You will need it.

Thursday morning, too, will be a busy one, the post-convention Board meeting, a special meeting for State and County treasurers desiring further elucidation of the treasurers' receipt blanks, and at 10:30 an informal round table presided over by the new president, the subject, "What Have I Gotten Out of the Convention?" At this meeting Mrs. McGlothlan will announce her committee chairmen and outline her plans for the coming year, and the subjects in the Question Box will be discussed, a sort of stock taking, closing the year's business and opening the new books.

Philadelphia as a historical and cultural center is the keynote of the entertainment planned for our guests. Except Monday, all afternoons and evenings will be devoted to pleasure, and a variety of excursions is offered to suit all tastes, all physiques, and all weathers. They include bus trips to Valley Forge and to Longwood, the beautiful estate of Mr. and Mrs. Pierre S. duPont, a boat trip on the Delaware, and visits to the Fairmount and Rodin Museums and to the Historical Society of Pennsylvania. The Museum authorities are delighted to provide docent service for those desirous of more than a passing glance at their treasurers, and the Historical Society will arrange a special exhibition for the week, including portraits, prints, and engravings, documents, silver, etc., from its unsurpassed collection of Americana. There will also be a brief historical address by Dr. Charles W. Burr of Philadelphia.

Wednesday will be a field day—the big Auxiliary luncheon—with guests and speakers from the A. M. A. and a beautiful musical program, the gift of the Delaware Auxiliary. In the afternoon the Philadelphia County Medical Society invites the women to be their guests on a bus trip through historic Philadelphia (a 10 minute stop at Independence Hall), Fairmount Park and Germantown to "Stenton," where the New Jersey Auxiliary invites us all to tea. "Stenton," the home of James Logan, Penn's friend, Secretary of the Colony, still stands just as it was built in 1728, the furniture of the period, the garden laid out as described by contemporaries. On Wednesday evening the Pennsylvania Auxiliary invites all visiting ladies to a reception in the superb Chinese Rotunda of the University Museum, a setting probably unsurpassed in any museum anywhere.

This meeting of the A. M. A. in Philadelphia is the first in 30 years, and the County Medical Society, desiring to mark so auspicious an occasion, and also in appreciation of the work of the Auxiliary, invites all members of the A. M. A. and the visiting ladies to be their guests at a supper dance in the Ball Room of the Bellevue, following the big meeting of the A. M. A. on Tuesday evening at the Academy of Music. The President's ball at the Benjamin Franklin Hotel on Thursday evening, to which all are invited, will close the formal festivities.

To those still able to rise from their beds on Friday morning there are offered a tour of Wanamaker's with luncheon in the Crystal Tea Room, or an all-day bus trip to Atlantic City, where the New Jersey Auxiliary will meet them for luncheon at the Claridge. This program includes also a visit to the new Convention Hall, an hour in a chair on the Boardwalk and plenty of time for window shopping or a swim.

And finally, every day and all day there will be a booth in the Roof Garden inscribed "As You Like It—Anywhere," where those wishing to golf, shop, go to Garden Days, or carry out any other pet project not elsewhere provided for may find information and assistance in making a profitable use of their opportunity.

Will you not reward our efforts by the largest and most enthusiastic women's attendance in the history of the American Medical Association?

Corinne Keen Freeman,
General Chairman.
(Mrs. Walter Jackson Freeman).

HENNEPIN COUNTY AUXILIARY

The regular meeting of the Auxiliary to the Hennepin County Medical Society was held March 18. Mrs. Martin Nordland, the President, was in the chair. A delightful group of piano selections was given by Miss Bernardine Cornea of the University of Minnesota. Dr. Meyerding gave an interesting talk on "The Relation of the Minnesota Public Health Association and the State Medical Association."

The annual Easter card party was held in the Assembly room of the Hennepin County Society on Easter Monday afternoon. Tickets for about 125 tables were sold. We are glad to say that it was a social and financial success.

Under the efficient leadership of Mrs. A. E. Hedback as chairman, with Mrs. J. M. Hayes and Mrs. C. W. Rucker and their committees, the Auxiliary has again been provided with funds to carry the philanthropic work of the group for the year. This year our particular venture is the furnishing of a room in the new home for patients with arrested tuberculosis from Glen Lake Sanatorium, which has come to the city through the generosity of Mrs. W. O. Winston.

The Auxiliary has ventured into a new field of activity, and has revived the noonday luncheon for the Medical Society, which was practically dead of inanition. The evident success of the experiment brought an appropriation from the Medical Society for needed equipment, but dishes and kitchen utensils cannot make a successful lunch-room, and the gratifying results are due to the devoted effort and interest of this group of women who have undertaken this work. It has become so popular that several committees of the Medical Society have asked that luncheons be served for their meetings.

The following committees have been appointed for the entertainment of the wives of the doctors at the State Medical meeting, May 5 and 6:

Registration—Mmes. H. J. Tunstead, J. D. Lyons, E. S. Strout, G. D. Nordin, W. B. Roberts, G. D. Eitel, O. S. Wyatt, and F. S. McKinney.

Transportation—Mmes. R. M. Rosenwald, Emil Robitshek, and E. J. Huenekins.

Program—Mrs. James Blake and her committee.

Printing and Publicity will be handled by Mrs. T. F. Quinby.

All registrations for visiting women will be taken care of at the Nicollet Hotel, beginning Monday afternoon, May 4. On Tuesday morning, May 5, at 10:00 o'clock, the annual Board meeting of the State Apxiliary will be held in parlors O, P and Q and a Dutch Treat luncheon at the Nicollet Hotel in the main dining room, to which all visiting women are invited. That same afternoon, Mrs. J. A. Watson and Mrs. J. S. Reynolds will be hostesses in the lounge of the Medical Society rooms to meet any visiting women who may wish to drop in for a game of bridge or an informal visit.

The banquet Tuesday evening, May 5, is open to all visiting doctors and their families. This will be held at 7:00 p. m. in the Ball Room of the Nicollet Hotel.

The annual business meeting and election of officers will be held Wednesday, May 6, at 10:30 a. m. in the assembly room of the Hennepin County Medical Society. This will be followed by a luncheon at the Woman's Club on Oak Grove Street, at 1:30. Transportation will be provided for all visiting women from the Medical Arts Building to the Club. The plans for the entertainment to follow the luncheon include a talk by Mr. H. A. Bellows, Vice President of the Columbia Broadcasting System, and music by the Thursday Musicale Ensemble which includes a number of our Minneapolis doctors' wives.

Mrs. S. H. Baxter.

NICOLLET-LE SUEUR AUXILIARY

An Auxiliary of the Nicollet-Le Sueur County Medical Society was organized April 8 at a joint meeting held at the Merchants Hotel, Jordan, in conjunction with the women of the Scott-Carver Society. Officers elected were: Mrs. Joseph O. McKeon, Montgomery, president; Mrs. W. W. Covell, St. Peter, vice president, and Mrs. Melvin Lenander, St. Peter, secretary-treasurer.

RICE COUNTY AUXILIARY

The March meeting of the Rice County Auxiliary was held at the home of Mrs. J. W. Murdoch, of Faribault, with Mrs. Haynes as assisting hostess. Mrs. A. M. Hanson, Faribault, president, presided at the business session, which was followed by a most amusing paper on "Methods of Quacks," read by Mrs. Haynes. A layette was made and donated to the Faribault and Northfield hospitals. Eight doctors' wives from Owatonna were guests at the meeting.

ST. LOUIS COUNTY AUXILIARY

The St. Louis County Auxiliary has been continuing its policy of philanthropic work throughout the year. The members are sewing on Red Cross articles at the regular meetings to help county Red Cross work. At the last meeting it was voted to send a working girl to the summer session of the University at Madison, Wisconsin. This University offers a short course each summer for working girls.

SCOTT-CARVER AUXILIARY

At a luncheon meeting held at Chaska, April 8, a Women's Auxiliary to the Scott-Carver Medical Society was organized. Mrs. S. S. Hesselgrave of St. Paul and Mrs. James Blake of Hopkins were guest speakers. The following officers were elected: President, Mrs. Bernard H. Simons, Chaska; vice president, Mrs. H. P. Fischer, Shakopee; secretary-treasurer, Mrs. H. E. Wunder, Shakopee.

STEARNS-BENTON AUXILIARY

On Tuesday, April 7, the Stearns-Benton Auxiliary met at the home of Mrs. J. P. McDowell of St. Cloud. The president, Mrs. Werner Hemstedt, was in the chair. The business session was followed by games of bridge. Since the first of the year several members have spent Friday afternoons sewing and mending at the St. Cloud Hospital.

WASHINGTON COUNTY AUXILIARY

The Women's Auxiliary to the Washington County Medical Society was entertained at a one o'clock luncheon at the University Hospital, Minneapolis, Tuesday, April 7. Other guests at the luncheon were the wives of the faculty members, who act as an auxiliary to the University hospital: Dean Lyon of the Medical School and Mrs. Lyon; Dr. O'Brien, and the head nurses of the hospital. Superintendent Paul Fesler, Dean Lyon and Dr. O'Brien gave short talks after the luncheon. The guests were then conducted on a tour through the hospital, and heard talks by Dr. Stenstrom, in charge of the radium department, and Dr. W. T. Peyton on cancer. The use of the respirator was demonstrated by Miss Clark. The Washington County Auxiliary will serve refreshments at Lakeview Memorial Hospital, Stillwater, May 10, to the visitors assisting the hospital superintendent. Mrs. J. W. Stuhr of Stillwater is president of the Auxiliary.

WEST CENTRAL AUXILIARY

The annual business meeting of the West Central Auxiliary was held at Wheaton, April 8. The following officers were elected: President, Mrs. Charles Bolsta, Ortonville; vice president, Mrs. A. L. Fitzgerald, Morris; secretary-treasurer, Mrs. Bert Karn, Ortonville. Mrs. C. F. Ewing of Wheaton, retiring president, presided at the session.

PROCEEDINGS OF THE MINNESOTA ACADEMY OF MEDICINE

Meeting of March 11, 1931

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, March 11, 1931. Dinner was served at 7 p. m. and the meeting was called to order at 8 p. m. by the President, Dr. J. S. Gilfillan. There were fifty-one members present.

Minutes of the February meeting were read and approved.

The scientific program of the evening was as follows:

Dr. A. R. Colvin (St. Paul) reported two cases and showed specimens.

Case 1.—Gallbladder in female pelvis. The patient, a woman aged 72, was first seen December, 1929, complaining of a mass in the lower abdomen; it was painless, not tender, and quite movable. She was concerned because of the tumor but did not want to consider surgery because it did not cause any pain. She was of the rather feeble type for 72, and surgery was not urged at that time. Nevertheless, a diagnosis of the nature of the mass was not made.

In April, 1930, she says she began to have some "heavy discomfort" in the abdomen, but no pain. In June, 1930, she says she began to have attacks of pain which she attributed to food, and she said that recently the tumor would disappear at times, and at these times she felt better.

When seen in early November, 1930, she had an attack of abdominal pain followed by jaundice. The pain continued intermittently, and the jaundice became deeper. The tumor had disappeared but she felt some pressure in the pelvis.

Examination revealed a fluctuating mass filling the pelvis. She had quite a kyphotic spine and a consequent approximation of the ribs to the iliac crest. There was no abdominal tenderness. The combination of jaundice and pain suggested common duct stone and the opinion was hesitatingly expressed that the mass in the pelvis could be an enlarged gallbladder.

Her enfeebled condition would render surgery extremely risky and was not undertaken. She died two week later. A partial autopsy showed a gallbladder about the size of a small grape-fruit packed tightly in the pelvis, and it was withdrawn by some effort. A small calculus was found in the common bile duct. The duct was not appreciably dilated; the cystic duct proximally was dilated to the size of a rather large sausage; distally, just proximal to the common duct, the cystic duct was surrounded by a mass of firm tissue and an area of indurated tissue, scirrhus-like in appearance, occupied the anterior wall of the gallbladder at about its center.

The histological examination of the tissue surrounding the cystic duct shows clearly an adeno-carcinomatous structure.

Case 2.—Tumor in the cecum. The patient, P. S., female, aged 34, complained of pain in the right lower abdomen, and of feeling "all in." In 1916 while at college she was ill for three months and miserable for some time afterwards. She had pain in the abdomen at that time. She came home from school and was in bed four months with tenderness, abdominal pain, fever, and chills. Following this she was better and had no fever, but had soreness and painful spells.

Five years ago during and after pregnancy she had pain and soreness. In March of 1930 she had fever and pain. During menstruation the pain was not so bad, but soreness was present all the time. She had spells of pain off and on about every two months, which made her feel "all in." She says they were something like "labor pains."

On examination there was some tenderness in the right lower abdomen. Bimanually there was a tender mass at the right of the uterus and thickening extending laterally.

At operation a midline incision was made below the umbilicus. On opening the peritoneal cavity a tumor was felt in the cecum, and found to be movable in the cecum. The cecum was densely adherent by old tough adhesions to the uterus and right tube. On separating these, the cecum was opened and the tumor exposed. Its attachment was to the posterior wall of the cecum, but it was found that the base of the tumor was continuous with the right ovary, which was, however, partly within and partly outside of the cecum.

To visualize the condition one would have to imagine an opening having been made in the posterior wall of the cecum. The diseased ovary now inserted into the opening with a subsequent closure by adhesions of the edges of the cecal opening to the diseased ovary and a consequent closure of the cecal opening in this manner. There must have been a gradual perforation of the cecal wall by the inflammatory mass containing the ovary.

The tumor mass inside the cecum was composed of tuberculous granulation tissue with some ovarian tissue at its base. The ovary was, of course, tuberculous, as was also the right fallopian tube. The cecum, except for the mass projecting through and into its lumen, was quite normal, the mucous membrane presenting no evidence of disease.

The closure of the opening in the cecum took place without untoward happenings and the patient is now free from pain and has gained 20 pounds.

Dr. C. N. Spratt (Minneapolis) reported the following case:

I wish to show a specimen of an eye containing a piece of steel which has been there for 67 years without causing any irritation or discomfort. This man consulted me for a cancer of the larynx, when it was noticed that the right eye diverged. Upon questioning, the patient stated that when he was 12 years of age, while he was in a blacksmith shop, something hit his right eye. An X-ray showed the presence of a foreign body, and in spite of the divergence it was localized to be in the bottom of the vitreous near the ciliary body. This man died in December, 1930, and through the courtesy of the family physician and with the consent of the deceased's sons, the eye was removed. This was sectioned and I have it here.

1. It shows that a foreign body may remain in the eye without causing irritation; the eye was blind but absolutely free from irritation.
2. The shadow is definite in the X-ray—the steel in the metallic form and not oxidized. It is probably a piece of wrought iron which resists corrosion.
3. It shows that even in a diverging eye, localizing a foreign body can be accurately done.

Dr. Walter E. Camp (Minneapolis) read his inaugural thesis entitled "The Pathology and Pathogenesis of Ocular Melanomata." Numerous lantern slides were shown.

DISCUSSION

Dr. John F. Fulton (St. Paul): I am more anxious to congratulate this Academy upon having Dr. Camp become a member than to enter into a discussion of his very excellent thesis. The doctor is not only a teacher of medical students, but a very competent instructor of the oculist himself. He has very competently and thoroughly discussed tonight one of the most important and serious subjects that the oculist is called upon to deal with. The title of the thesis is somewhat misleading. Melanomata, as defined by Collins, is an innocent pigmented growth in the uveal tract which may become malignant. These apparently innocent accumulations of pigmented cells, by trauma of some unknown cause, at times take on a malignant growth of the fulminating type which may not only destroy the patient's eye, but also his life. The pigment proliferation usually originates from the epithelium of the deeper structures but may also originate from the choroidal cells.

There is a condition closely related to this, namely, melanosis, which is a deposit of pigment in structures where it is not usually found, as the cornea and conjunctiva. This condition is not necessarily malignant but is potentially dangerous, for the literature on the subject demonstrates that 30 per cent of such cases become malignant.

Dr. E. M. Jones (St. Paul) read a paper and reported cases of Phlegmonous Enteritis.

DISCUSSION

Dr. H. B. Zimmermann (St. Paul): I have never seen a case such as Dr. Jones described. In regard to the second case, not long ago I had a man come to the hospital with pain in the right lower abdomen, and fever. A diagnosis of appendicitis was made and at operation a small inflamed appendix was found. Just proximal to the ileocecal valve he had a peculiar condition. It looked like sigmoid. It felt exactly like the sigmoid and contracted normally to stimulation. The wall was about one-half an inch thick and fairly normal. It looked like a bit of intestine that had worked against obstruction for a long time. Since then he has had two other attacks of cramps in the right lower quadrant of the abdomen.

In going over the man's history, he told me that he had had a very severe attack when he was in the army. He had violent pain but the surgeons did not think it was exactly appendicitis and were rather confused about it. He got well without an operation.

I spoke to Dr. Jones about this patient and he suggested that it might have been phlegmonous enteritis.

Dr. A. R. Colvin (St. Paul): I showed a specimen here some two years ago of phlegmonous duodenitis which bears out the remark made by Dr. Jones, that this is a fatal disease. My patient was a woman who entered the hospital very acutely ill. It was thought she had some upper abdominal trouble. At operation the duodenum was found to be thickened and there was general peritonitis and a phlegmonous inflammation of the duodenum extending from the pylorus to the duodenal jejunal junction, and the mucosa was fairly studded with small superficial ulcers.

In looking up the literature at that time, I found that Melchior, writing on Surgery of the Duodenum in Neue Deutsche Chirurgie, could find only 10 cases reported in the literature. Dr. John Noble told me later that the newer references were more numerous.

Dr. John Noble (St. Paul) (by invitation): Phlegmonous inflammation of the gastrointestinal tract is a rare disease. It is found more frequently in the stomach and large intestine than in the small intestine and, as Dr. Jones has pointed out, the proximal portions of the small intestine are more commonly involved than the distal portions. While the rarity of this disease cannot be questioned, it undoubtedly occurs more frequently than the reports in the literature would indicate. In our series of autopsies at the Ancker Hospital we have seen two cases of phlegmonous enteritis. One of these Dr. Colvin mentioned and the other was the first case reported by Dr. Jones.

The etiology of the condition is not clear, but as a rule there are certain predisposing factors, the most common of which are preexisting ulceration of the mucosa, general sepsis, intestinal obstruction, or trauma. Dr. Jones' first case is evidently a manifestation of a systemic infection, while his second case appears to have followed a partial intestinal obstruction.

I think the principal value in reporting these cases is to familiarize the practicing surgeon with the gross appearance of the lesion so that he will recognize it readily when he encounters it at the operating table. Once having seen the lesion it can be confused with few other conditions. It slightly resembles a scirrhus-carcinoma but its inflammatory character and the difference in consistency make this differentiation easy. It may also be confused with a diffuse leukemic infiltration or a diffuse lymphosarcoma, but in both of these conditions evidences of inflammation are usually absent.

From the cases reported here this evening there seems to be definite clinical evidence that phlegmonous enteritis can vary considerably in intensity and that, in some instances at least, recovery occurs without radical surgical interference. The recognized surgical procedures are resection of the involved gut; or, intestinal anastomosis, short-circuiting the inflamed segment. The first procedure seems more rational since it removes the focus of infection and reduces the possibility of general peritonitis, and these cases die of a general peritonitis. The suggestion made by Dr. Jones that an enterostomy proximal to the lesion might be the method of choice in some instances, would seem to be more reasonable than a short-circuiting anastomosis.

Dr. A. E. Benjamin (Minneapolis): I want to report one case which is rather interesting in this connection, which I operated about a year and a half ago. The patient was a farmer's son, 25 years of age, who gave a history of having severe pain and distention of the abdomen, with nausea and vomiting, and some fever. The pain was not confined to the region of the appendix but more to the left and opposite the umbilicus. He came in to see me and I put him through quite an examination, including X-rays, but could not determine just what the trouble was. I decided to do an exploratory operation. A median incision, going by the umbilicus, was made and I found two sections of the lower portion of the jejunum, one about 6 inches and the other about 8 inches, covered with fibrinous exudate. This was more or less acute in character because he had just gone through an attack, and there was definite partial obstruction. There was a question as to whether or not to do a resection. I did not think it was malignant; there was no diverticulitis nor any other inflammatory condition in the abdomen that could account for this pathology. So I separated a few of the adhesions and sewed him up. He was put on a special diet and sent home. He has had one attack since, but as long as he keeps on a very careful diet, with no coarse foods, he remains in very good condition and apparently perfectly well. That was a case in which I think the right treatment was to let him alone.

Dr. Arnold Schwyzer (St. Paul): While Dr. Jones was reading his paper three cases of this type came to my mind. I wonder whether the second case Dr. Jones described was really phlegmonous enteritis. It may have been a simple inflammatory thickening. In the course of operation for acute appendicitis in two cases, I saw an area of the lowest ileum thick, fleshy and rigid. In one case this area was about 6 cm. long, ending a few centimeters above the ileocecal valve. In the other case the involved area was from 12 to 15 cm. long. We removed the appendix and the patient got well without any trouble, though we had been quite apprehensive as to the outcome. In a third case where we had a mass in the cecum we found that the process of hardening and thickening reached about 10 cm. up into the ileum. An ileocolic resection was made. The specimen showed it was tuberculosis. That case came to good recovery.

Dr. Jones (in closing): I appreciate very much the discussion of this paper. It seems that the cases Dr. Schwyzer mentions fall in the group of phlegmonous enteritis but undoubtedly of less virulence. In the second case I reported, it seems that resection would have been quite radical and therefore I just relieved the obstruction. Resection is advocated as the operation of choice, but, in view of the fact that anastomosis of the intestine above and below the lesion without resection has led to recovery, it seems to me that in cases where a resection is desirable, but not feasible, an enterostomy placed proximal to the affected bowel would be desirable.

In mild cases where one can find definite cause for the infection I believe that merely removing the exciting cause would be sufficient.

Dr. Arnold Schwyzer (St. Paul) reported the following case:

A man came to my office with a swelling in the midline in front of the hyoid and thyroid cartilages—a plain cast of cyst of the thyroglossal duct. It could be removed without breaking it. It was thin-walled, the content slimy. At the upper posterior pole toward the corpus of the hyoid bone it had been firmly adherent. We know that there is usually a little tract running through the hyoid bone, or just grazing the periosteum. It is, therefore, unsafe to leave this median portion of the hyoid bone. Sistrunk quite properly advised to follow the track of the thyroglossal duct up into the tongue. We resected the hyoid bone and found a thin tract which we followed for about 2 or 2½ cm. It could be easily demonstrated as a grayish cord-like structure. It then became very thin and tore off (shown on drawing). Not being quite satisfied, I forced the finger into the musculature of the tongue and then with one finger in the mouth I palpated the parts between the two fingers. To our surprise we found a round mass of the size of a large cherry stone. With fine artery forceps inserted into the wound, the mass was gotten hold of. It seemed to break and we saw a little lake of whitish slime. The area in the musculature of the tongue was excised with scissors. This little mass was located directly under the mucosa of the tongue. Microscopically there was a larger cyst, in the neighborhood of which there were several tortuous little tubules with pavement cell lining. The mass was located under the foramen cecum of the tongue, where the thyroid anlage originates. Had this congenital epithelial formation gone to a little further development, we would have had a lingual thyroid. It has been observed that a lingual goiter would grow after thyroidectomy. In one reported case, the tumor grew in a compensatory sense. But it grew so much that it made trouble and had to be removed and, after its removal, it seems that myxedema showed up.

The meeting adjourned.

R. T. LaVake, M.D.
Secretary.

PROCEEDINGS OF THE MINNEAPOLIS SURGICAL SOCIETY

Meeting of March 5, 1931

The regular monthly meeting of the Minneapolis Surgical Society was held in the Lounge of the Hennepin County Medical Society on Thursday evening March 5, 1931. The meeting was called to order at 8 p. m. by the President, Dr. A. T. Mann. There were twenty-seven members present.

Minutes of the February meeting were read by the Secretary.

The President and several members announced the receipt of letters from Dr. Clay Ray Murray thanking them and the Society for the courtesies shown him on his visit to Minneapolis. The President also stated that the Council recommended the election of Dr. Murray to Honorary Membership in the Minneapolis Surgical Society, and upon vote of the Society this was unanimously carried.

Upon ballot the following officers were elected for the ensuing year: President, Dr. J. Frank Corbett; vice president, Dr. E. K. Green; secretary-treasurer, Dr. H. O. McPheeters (re-elected); council member, Dr. Martin Nordland.

The Scientific Program of the evening consisted of the following:

Dr. Willard White read a paper on "Traumatic Appendicitis."

DISCUSSION

Dr. J. Frank Corbett said that a number of years ago he read Kelly's book on the Vermiform Appendix and Its Diseases, and he thought the author stated about all there is to be said near the close of the book. As nearly as Dr. Corbett could remember, it was this—"Traumatic appendicitis does not occur in a normal appendix, but it may occur in an appendix that previously has been the site of an infection." Dr. Corbett was of the opinion that this was a reasonable view of the situation and brings one back to the question of latent infection that has been flared up by some unusual occurrence. He had had the opportunity of seeing only a very few cases of traumatic appendicitis but had had extensive experience down on the border in the concentration of troops. There were many hardships in long marches and knocking around and among the regular army men there was practically no acute appendicitis. Then there was another group of recruits who had been taken from civil life, and the incidence of appendicitis among these (very many giving no history of previous attacks) was extremely high. In other words, all of these men were fed the same and lived the same but the change in diet and living for these men who were not accustomed to such rough hard life was sufficient to flare up a more or less latent infection which they may have had. Dr. Corbett said that this experience which he had had made him more willing to believe that trauma is an exciting factor in the production of appendicitis in a predisposed individual.

Dr. Webb asked if some of Dr. Howard A. Kelly's fifty cases did not contain nut shells, pins, as well as numerous fecal concretions.

Dr. O. H. Wangensteen said that most everyone would concede that trauma that severs the appendix or its mesentery or that causes a bursting of the appendix would constitute a traumatic lesion of the viscus. Concerning the obstructive appendicitis which Dr. White spoke particularly about as being engendered by trauma, there is adequate cause for debate. Dr. White postulates that a blow on the abdomen increases the intraluminary pressure in the appendix in such a manner that a fecalith may become impacted in its lumen. This conjecture, however, demands proof. It is well known that no such happening occurs in acute or chronic types of bowel obstruction of the lower colon. There undoubtedly is some difference in the displacement occurring under the influence of gradual distention and that attending sudden changes of pressure. However, in simple obstruction of the sigmoid flexure, perforation or other changes such as gangrene of the proximal bowel may occur due to the distention of the proximal bowel. Shimodaira of Kocher's Clinic, in 1911, indicated that the lesion that is responsible for a simple obstruction assuming strangulation features is usually a carcinoma of the sigmoid flexure, and the perforations, ulceration or gangrene are usually observed in the cecum, occasionally in the terminal ileum, and at times in portions of the colon nearer the point of obstruction. The reason that these distention ulcers occur in the cecum is easily apparent. If one takes two toy balloons of equal size but of unequal texture and attempts to distend them by blowing, the thinner one always inflates with greater ease and ruptures more easily. Similarly, the cecum has the largest diameter of the entire bowel. The appendix, with a relatively thick wall and small lumen, would not distend easily. Dr. Wangensteen had never heard of a perforation of the appendix from an occlusion of the sigmoid flexure, though its occurrence in the cecum is well known.

Dr. Wangensteen stated that Wilkie, of Edinburgh, has pointed out that obstructive appendicitis due to the impaction of a fecalith in the lumen of the appendix is a serious form of the disease, for the appendix often ruptures before there is an inflammatory reaction around it. It would not appear, however, that Dr. White has adduced any evidence to indicate that in trauma a fecalith may become lodged and impacted in the lumen under the influence of a force exerted upon the abdominal wall. No one will dispute the traumatic origin of appendices severed under the influence of trauma but Dr. Wangensteen felt there was no evidence to substantiate Dr. White's conclusion relative to the group of cases that he has described.

Dr. Mann asked Dr. White if, when speaking of a ruptured appendix, he meant a real case.

Dr. S. H. Baxter asked if any experimental work had been done along this line. What Dr. Wangensteen has said would apply if one assumed that the cecum is distended. But if the cecum in flaccid and simply filled with fluid it is conceivable that the force would be expended equally in all directions and might be forced into the appendix and rupture the appendix itself. Dr. Baxter felt that it would be a matter for experimental work to decide.

Dr. Martin Nordland asked Dr. White if he had access to the General Hospital records in this connection. He said that in about 1913 when at the General Hospital he had assisted Dr. Wilcox in operating on a boy about eight years old who had been hit in the abdomen by a baseball. A diagnosis was made in that case of traumatic ruptured appendix.

Dr. J. M. Hayes recalled one case which was quite evidently of traumatic origin. A number of boys had gathered at this boy's home to celebrate his birthday. As they were struggling to lay him across a box to paddle him the area over the appendix was hit hard against the corner of the box. He collapsed at the time, then seemed quite well for a time. Less than an hour afterward he complained of severe pain in this area. He was taken to the hospital about twelve hours later with what appeared to be a very severe case of appendicitis. The family would not consent to an operation immediately but a little later (about 15 or 16 hours after the accident) he was opened and the appendix was found to be gangrenous in the distal half. The patient had never had an attack of appendicitis before and was perfectly well and healthy up to the time of the accident.

Dr. Mann asked Dr. Hayes if that case was one with or without pus.

Dr. Hayes replied there was no gross evidence of free pus.

Dr. Kenneth Bulkley was of the opinion that the arguments in favor of appendicitis being of traumatic origin were not conclusive inasmuch as the interpretation of the abdominal pain in most of the cases cited was not properly made. To argue that because following abdominal trauma an individual immediately developed pain and that hours or days later definite symptoms, in addition to the symptom of pain, developed indicative of an appendicitis, and that at operation a definite appendicitis was found, is not conclusive evidence that the trauma sustained was either a direct cause or an exciting factor in the development of this appendicitis. A severe blow upon the abdomen concededly causes pain, particularly if the individual receiving such a blow is not prepared for it and has not set his abdominal muscles on guard. Even with his muscles on guard the pain immediately following a severe blow may be intense. This pain is due probably not only to contusions of the skin, subcutaneous fat and muscles of the abdominal wall but quite possibly also due to contusion of the parietal peritoneum. If the blow causing this pain is of sufficient severity to cause intra-abdominal injury one of four intra-abdominal lesions is apt to result, namely: (1) rupture of the spleen; (2) rupture of the liver; (3) laceration of the mesentery; (4) pneumatic blow-out or actual division against the vertebral column of the jejunum.

Other injuries, of course, are recognized but these four are probably the most common. Dr. Bulkley had never personally seen a case himself nor did he remember having encountered in the literature a case following abdominal trauma in which on opening the abdomen direct evidence of injury to the appendix was found, with the exception possibly of such cases of severe crushing injuries in which injury of the appendix was coincidently found with multiple severe intra-abdominal injuries. Immediate pain following a blow upon the abdomen is, as already noted, probably due to abdominal contusion; and just because this patient later develops symptoms of appendicitis, it does not, in Dr. Bulkley's opinion, seem reasonable to assume that the development of this appendicitis is due to the blow. All appreciate the rapidity with which an acute attack of appendicitis may develop. Dr. Bulkley recalled vividly the instance of a young boy operated upon in a hospital many years ago for hemorrhoids. This boy had been under hospital observation for five days with normal pulse and temperature. At 8 o'clock in the morning this boy developed abdominal pain. Dr. Bulkley operated upon him four hours later, removing an appendix gangrenous throughout practically its entire length. Let us assume that an hour previous to the onset of pain the nurse had by accident dropped this boy's breakfast tray, striking him upon the abdomen. Under such conditions, the proponents of traumatic appendicitis would probably have argued that this was a case of traumatic appendicitis! If one studies carefully the histories of the cases of Dr. Kelly, quoted by Dr. White this evening, one can find but little argument, assuming the theory of abdominal contusion to be correct, to classify any of these cases as real traumatic appendicitis. It was Dr. Bulkley's opinion that development of appendicitis hours or days following abdominal trauma was purely fortuitous.

Dr. J. H. Rishmiller stated that it was the general practice to remove an apparently normal appendix when an intra-abdominal operation had been undertaken for a definite pathological entity. When opening the lumen one may find animal parasites, especially the Oxyuris vermicularis or a fecalith.

He stated that a hard blow over the right lower abdominal quadrant may easily light up a fulminating inflammation of the vermiform appendix in one who previously had considered him- or herself symptom-free Physicians are all schooled in the primary etiological factors which are the forerunners of appendicitis. In other words, one with pinworms or fecal concretions has had a definite latent appendicitis. Consequently, trauma can be regarded only as an indirect cause and not as a direct cause. Dr. Rishmiller stated that trauma was coincident with latent appendicitis, resulting in suppuration with all its possible sequences. This, Dr. Rishmiller believed, was now the general status of opinion of traumatic surgeons towards traumatic appendicitis.

He stated that so far a blow on the neck had not been claimed to have been the cause of traumatic tonsillitis nor had a blow on the abdomen, causing intra-abdominal contusion, been the forerunner of typhoid fever, but nobody knew what effect the rapid progress of the times would have on the mental attitude of the public. He had never seen a case of primary traumatic appendicitis. He had had men come to him who thought they had strained the abdominal muscles; they had pain over the right lower abdominal quadrant and some thought they had a hernia. He said it was sometimes difficult to persuade them that they had appendicitis and not a muscular lesion.

Dr. Rishmiller reported a case of indirect injury that occurred in 1910: Two men were riding on an electric truck and probably did not know what they were doing, due to the fact that they were under the influence of Bacchus, being so vivified that they ran into one of the "Soo" trains which was going at about thirty miles an hour. Both men were pitched forward. One man came out practically whole; the other had a scalp wound four inches long on the vertex. He was taken to the Swedish Hospital, where Dr. Rishmiller examined him for fracture of the skull, but could detect none. He sewed up the scalp wound, put the patient to bed and kept close watch of his cranial injury. The patient had no other external injury. His temperature, pulse and respiration had been taken with the intent of carefully watching his intracranial condition. The patient had been fairly comfortable during the night but the next morning, following a soapsuds enema, he became suddenly worse and died, and the question naturally arose, What did he die of? The speaker had talked with the man about five minutes before he died and the patient stated that he had such severe abdominal pain that he could not endure it. A partial autopsy was done which revealed a rupture of the small intestine. What had been the cause of the rupture of the intestine? This condition Dr. Rishmiller had not seen mentioned in the literature. On the right side, near the appendix, all the intestines had been agglutinated by chronic adhesions. It was his opinion that from the momentum of the patient striking on his head, the intestines had been suddenly thrown forward and then suddenly stopped, and this produced a rent in the intestine on account of the chronic adhesions, due evidently to an old lingering appendicitis. Dr. Rishmiller stated that very often we have indirect injury to deal with and this was one condition in which there was absolutely no direct injury to the abdomen. He said that indirect injury was frequently just as enigmatic as were subjective symptoms.

Dr. Webb said that two months ago the question of traumatic hyperthyroidism was discussed in this society and now it appears that appendicitis is also being included in traumatic surgery. He said that he could conceive of traumatic appendicitis if at operation the appendix were found lying across the vertebral column and injured by being crushed between the spine and some hard object.

Dr. Webb recalled the Bastedo test in which the colon was routinely inflated and then suddenly further inflated in suspected chronic appendicitis in order to elicit pain in the appendix. He had never seen any ill effects from this procedure, which was a routine test a few years ago.

Dr. Wilard White (in closing) said he appreciated the discussion and felt that the subject was important enough to warrant very careful consideration. He realized that bringing up the question of trauma to the abdomen and subsequent development of appendicitis might furnish occasion for plenty of argument in a great many cases but the main purpose of this discussion was to call attention to the fact that there really is such a thing as traumatic appendicitis and the mechanism of its production can be easily understood. He mentioned the fact that other writers, particularly Luddington, had called attention to the fact that confusion about this subject sometimes arises concerning what is meant by trauma and traumatic appendicitis. Small foreign bodies within the appendix might give an irritation to the mucous membrane of the appendix and when the appendix is removed and examined under the microscope the pathologist might return a report of foreign body in the appendix with production of a traumatic appendicitis, whereas from the clinician's standpoint this would not be a traumatic appendicitis. In this article he means traumatic appendicitis is an appendicitis which develops following an injury to the abdomen in the form of some external violence or unusual force or strain being applied to the abdomen and, as stated in the main substance of the article, this force causes increased pressure in the cecum forcing the material into the appendix. Under suitable conditions when this fecal material cannot be returned to the cecum and is retained in the lumen of the appendix, stasis results with subsequent distention of the appendix and interferes with the blood supply, so that gangrene of the wall of the appendix follows. This is what is meant in this discussion by traumatic appendicitis. It is no argument to state that many people receive blows on the abdomen and do not develop appendicitis as a result, as the condition within the appendix has to be suitable so that a definite train of events can occur.

Dr. A. T. Mann presented a case of fracture of the clavicle in which there was an auto-graft two inches long. It was four months old, and had healed firmly with a perfect line for the clavicle. The clavicle was slightly increased in size in the region of the fracture and the auto-graft, as was to be expected. (Patient present.)

The fracture at the junction of the middle and outer thirds of the clavicle had been received in a football game in which the knee of the opponent had slid under the shoulder guard and directly upon the region of the clavicle. This had broken the bone and snapped out a piece of the clavicle two inches long and almost the entire width of the bone, leaving only a thin, curved, spear-like projection on the upper margins of the two main fragments with the loose two-inch fragment between and below them with all of the parts considerably displaced.

At the time of the operation, the loose fragment was found entirely detached from all tissue and came out of the wound freely into the hand. This fragment was the best bone-graft one could have. It would fit into the defect after reduction of the displacement and it belonged to the patient with all his personal idiosyncrasies of serum and of cellular tissue. So it was used as an auto-graft. The bones were "wired" into place with forty-day chromic gut. Dressings were applied and the shoulders were fastened to a straight splint placed dorsally between them. There was firm union now at the end of four months and the clavicle is smooth and the outline seems practically perfect.

Dr. Mann stated that three months to four months seems to be the time which a bone graft of this size takes to be entirely replaced by new bone. He spoke of the care with which a bone graft ought to be handled.

Some small portions of the graft continue to live and to help produce bone although most of the graft is replaced by bone formation growing into it as it gradually melts away. For this reason he thought that, theoretically at least, a living graft is better than a preserved graft, and an auto-graft is better than a piece taken from another person or an animal because of the identity of its cells and serum reactions.

In handling a graft at the time of an operation, Dr. Mann thought there were two main considerations to keep in mind to prevent damage to the graft and loss of vitality: first, to put it into surroundings as nearly normal as possible, and, second, to prevent its becoming dry. Both of these can be accomplished by placing the graft immediately into normal saline at body temperature, sometimes, even better, by covering it completely under one of the operative flaps until it is used.

In regard to the method of bone replacement when a graft is used, Dr. Mann referred to a series of experiments made by him in 1915-16 to determine the behavior of auto-grafts of the condyles in knee joints. He read one of the conclusions given in the reprint, which referred to this question, as follows: "The main replacement of the bone in the trabeculæ seems to take place directly from bone cells without the preliminary formation of cartilage, and the dead portions of the trabeculæ seem to be absorbed in a line immediately adjacent to the new growing bone without the intervention of special osetoclasts."

Dr. R. F. McGandy read his inaugural thesis entitled "Electrical Burns and Shock."

DISCUSSION

Dr. J. F. Corbett said he would like to ask if there is any rule as to the number of hours respiration should be kept up in these cases.

Dr. A. L. Herman stated that there is one other measure which is of value sometimes in these cases and that is subcutaneous injection of oxygen. When there is merely paralysis of the respiratory muscles quite large amounts of oxygen can be absorbed. The oxygen can be filtered through sterile cotton and administered just as one would give normal salt solution. It is very readily absorbed and may tide the patient over the period of respiratory paralysis.

Dr. Mann asked whether these electrically shocked men have a change in their time of development of rigor mortis.

Dr. Webb stated that in a movie shown to the employees in the electrified section of the Great Northern Railroad the employees are instructed to keep up artificial respiration in apparently electrocuted persons even after the doctor tells them they may cease.

Dr. McGandy (in closing) said concerning Dr. Corbett's discussion that power companies have spent tremendous sums of money in order to reduce mortality rates in electrical accidents. Every man is taught the prone pressure method of artificial respiration. This teaching is not merely a lecture course, but every man is required to actually demonstrate prone pressure on his fellow employees. The greatest trouble that is encountered in this region is apparently interference by physicians who are not thoroughly acquainted with electrical shock. They usually stop artificial respiration too soon. The employees, on the other hand, are taught to continue artificial respiration until rigor mortis sets in if breathing does not start sooner. Many cases are reported where breathing followed hours of artificial respiration.

Concerning the subcutaneous injection of oxygen, Dr. McGandy stated that while it is a good measure its use is impractical. In the first place, to secure the best results it should be started and used immediately, which means that the apparatus should be in the hands of many employees. In the second place, no employee would know how to use it properly, it being a purely medical measure. On the other hand, in large institutions where a doctor is in constant attendance, it is a practical measure.

Concerning the change in time of rigor mortis, Dr. McGandy stated that in his review of the literature this question was not answered.

The meeting adjourned.

H. O. McPheeters, M.D., *Secretary.*

WHAT ONE NEWSPAPER DID TO PROTECT THE PUBLIC AGAINST CHARLATANS

Last July, the Philadelphia *Record* started to look into the problem of medical quackery and published a most interesting and enlightening series under the general title "Bootlegging the Healing Arts." The *Record* called for no help from the medical profession, either locally or nationally. The *Record* reports that thirty-seven cases were brought up with thirty-five convictions. (Jour. A. M. A., March 14, 1931, p. 883.)

CONSULTATION BUREAU

(Continued from Page 451)

number, no demonstrable organic change can be found (even after an autopsy), and it is necessary to write down "that the cause of death is undetermined."

4. *Question.*—I have a patient who develops a small, tender swelling in the right axilla with nearly every menstrual period. There is a small, palpable lump in the intermenstrual interval, but tenderness seems to go away when menstruation is over. What is the condition?

   Answer.—The usual cause of tender painful swellings in the axilla in connection with menstruation are nodules of supernumerary breast tissue. The treatment is removal of the mass. Such masses may be the seat of any disease common to the breast (cyst and tumor). As a general rule, they are no more apt to become malignant than similar breast tissue in the usual location.

PROCEEDINGS OF THE MINNEAPOLIS CLINICAL CLUB

Meeting of February 12, 1931

The regular monthly meeting of the Minneapolis Clinical Club was held in the Hennepin County Medical Society Lounge in the Medical Arts Building on Thursday evening, February 12, 1931. Dinner was served in the Auditorium at 6 o'clock and the meeting was called to order by the President, Dr. Moses Barron, at 7 o'clock. There were 20 members present.

Minutes of the January meeting were read and approved.

The Secretary read the Annual Report of the Treasurer, which was accepted and placed on file.

Upon ballot the following officers were elected for the ensuing year: President, Dr. F. H. K. Schaaf; vice president, Dr. A. H. Beard; secretary-treasurer, Dr. H. B. Dornblaser (reëlected).

The scientific program of the evening was as follows:

Dr. S. R. Maxeiner reported a case and showed specimen of a "Mucocele of the Appendix."

The patient, John R., 71 years of age, male, married, and by occupation retired, was first examined by us on February 7, 1931.

He had had no previous illnesses except frequent colds. Fifteen years ago he fell and developed a rupture, but had had no operation. One year ago an X-ray was taken for the present complaint, and this was negative. There was no history of tuberculosis in the family. The patient's wife had died of cancer; there were five children.

His present complaint was a painless movable tumor in the right abdomen. Four or five years ago the patient first noticed a small tumor in the right abdomen which seemed to be elusive and could be felt in different areas but was painless and small. During the past two years the tumor has progressively become larger and a little sensitive on deep pressure. There had been no loss in weight nor any gastrointestinal disturbances. The bowels moved once a day regularly without a cathartic, and there was no blood in the stools. The only complaint was nocturia two or three times a night occasionally; no frequency, but there was a great deal of difficulty in starting the stream at times. There was no hematuria; no chills or fever.

The physical examination showed a well-nourished male, 71 years of age, who did not appear acutely ill. Temperature, pulse and respiration were normal; blood pressure 110/50. The examination was negative except for the following: The throat was reddened, with tonsils present. Extremities were normal except for a large lipoma over the right thigh. Rectal examination revealed a very large prostate, hard and very smooth. There was no tumor mass in the rectum and the mass which was palpated in the abdomen could not be felt through the rectum.

There was a rounded tumor mass about 5 inches in diameter which was palpable in the right lower quadrant and freely movable from the kidney region down to the pubis. It was only slightly tender on palpation and elicited the consistency of encapsulated fluid. The second day after the patient's entrance into the hospital, abdominal palpation revealed no abdominal mass. It was only by changing the patient's position and permitting the mass to gravitate out of the pelvis that it could again be palpated. No other tumor masses were palpable. The organs were not palpable.

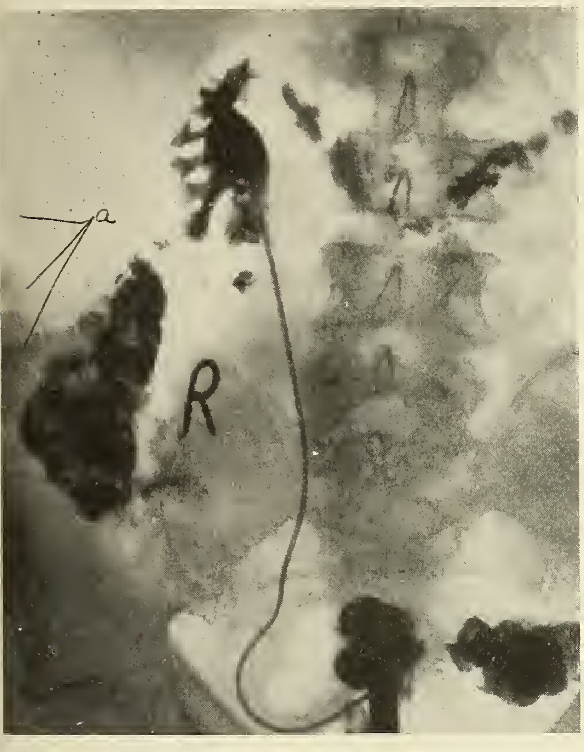

Fig. 1. Shows the colon partially filled with barium, a pyelogram of the right kidney with an opaque catheter in the ureter. The tumor is displaced downward and held by the operator's fingers (a). In this manner a tumor of the kidney could be definitely ruled out as three of the operator's fingers can be seen above the tumor and below the kidney.

The patient was admitted to the hospital on February 8, 1931. The report of the X-rays taken February 9th is as follows: "A barium enema was administered under fluoroscopic control. The solution passes all the way into the terminal ileum. There is no evidence of growth, filling defect nor any displacement of the colon from the mass within the abdomen. Conclusions: No evidence of pathology of the colon and no evidence of displacement of the colon by the intra-abdominal mass."

On February 10, 1931, on account of the history of difficulty in starting stream, the finding of an enlarged prostate and a great deal of pus in the urine, and in spite of Uroselectan, it was deemed advisable to do a kidney examination. Cystoscopy revealed a very large prostate with a moderate degree of cystitis. Both ureteral openings were normal. Specimens from each side revealed only a few pus cells. A pyelogram of the right kidney was made, using 7 c.c. of 30 per cent solution of sodium iodide. Report: "A pyelogram was made of the right kidney. This shows no defect in the pelvis or calices. Conclusions: Normal right pyelogram."

The preoperative differential diagnosis rested between chylous cysts, enteric cysts, intraperitoneal cysts of nephritic origin, and dermoid cysts or teratoids as classified by Ewing. A cyst in this instance might have involved the peritoneum, the mesentery, or the omentum.

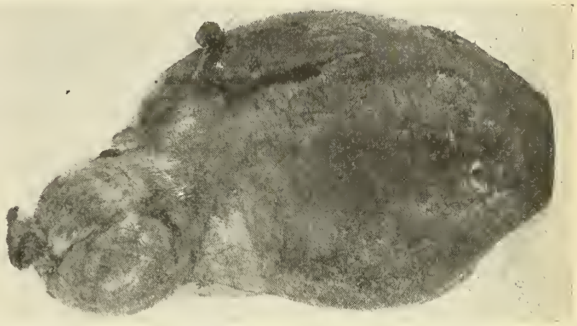

Fig. 2. Mucocele of the appendix. At the end is the ligated base of the appendix; in the midportion the ligated mesoappendix. The mesoappendix can be seen to run along the superior surface.

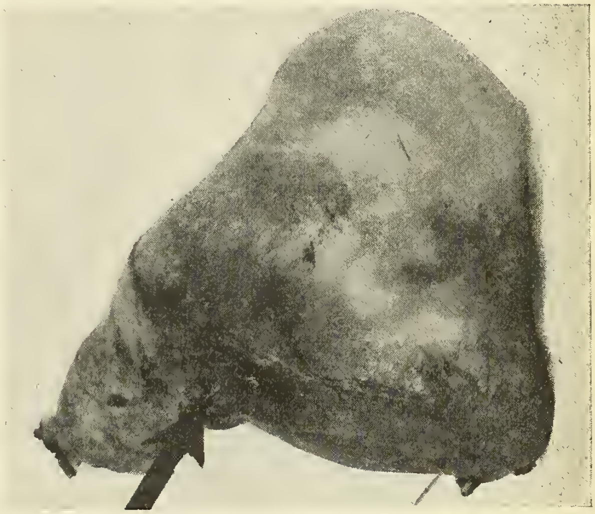

Fig. 3. A side view of the tumor showing the enormous dilatation that had taken place, and the extremely thin wall is suggested by the whitish area. The tied off mesoappendix is designated by the arrow.

Operation: Under local anesthesia through a right rectus incision, the abdomen was opened and a large white tumor resembling in appearance an ovarian cyst was found to lie within the pelvis. The mass was delivered and adhesions between it and the ileum, cecum and omentum were separated and, after a very careful check, the tumor was found to be attached to the cecum by a small stem and to have a mesentery so that the mass was immediately recognized as an enormously dilated appendix. The mesoappendix was clamped and tied and the base treated in the usual manner for an appendix. The abdomen was closed without drainage and the patient made an uneventful recovery.

Pathological report: Section from mucocele of appendix: "The walls of the appendix are much thinned out. Muscle layers are indistinct and show a hyaline-like degeneration. It is lined with a columnar epithelium. There is some infiltration with lymphocytes, some plasma cells and eosinophiles."

The gross specimen measured 5 inches in length and 3 inches in thickness.

DISCUSSION

Dr. R. G. Allison: The mass was freely movable and was moved with the bowel. We felt, as Dr. Maxeiner did, that it was probably a mesenteric or omental cyst.

Dr. Moses Barron: I have seen two other specimens just like this one. The specimen is typical of mucocele of the appendix. The lumen of the appendix is markedly distended and the wall very much thinned. It contains a mucoid substance and might be considered a retention cyst of the appendix.

Dr. Allison: I would like to ask just what is the difference between a mucocele and a cyst?

Dr. W. E. Camp: I think they are essentially the same; the mucoceles I have seen are simply cysts with very thin walls.

Dr. C. A. McKinlay reported a "Case of Pulmonary Abscess Following Tonsillectomy, Terminating in Fatal Hemoptysis." (To be published in the Journal-Lancet.)

DISCUSSION

Dr. A. H. Beard: I think Dr. Camp had a case similar to this, where the sinuses were involved and the patient had an abscess in the chest. Tubercle bacilli were not found in the sputum but rest in bed for a period of a month or two cleared the condition. Local anesthesia was used in that case.

Dr. W. E. Camp: That was an acute sinus case. The patient had an acute posterior ethmoiditis and sphenoiditis. The antrum was irrigated, but found clear. We went into the posterior ethmoid and sphenoid and found thick creamy pus in both. The patient got along very well for five or six days, then developed an abscess in the right lung that manifested itself by a large frank hemorrhage. The abscess drained well, and healed without further trouble. After leaving the hospital the patient developed a paralysis of the external rectus of the right eye. This disappeared gradually, and she has been well ever since.

Dr. F. W. Wittich: I saw one case like this about five years ago, of a dentist's wife who had almost a parallel history. She had a tonsillectomy under local anesthesia and developed a pulmonary abscess with repeated profuse hemoptysis, dying from a hemorrhage. I am inclined to think that these cases are not due to direct aspiration under local anesthesia but that they are mostly blood-borne affairs. I would like to raise that question whether any other members have had any evidence on the subject. Where the suppuration is quite extensive hemoptysis may be very sudden and fatal.

Dr. F. H. K. Schaaf: In favor of Dr. Wittich's suggestion that these cases may be blood-borne, I can cite one case which occurred at the University Hospital. This boy had had a sore throat but no operation. A few days later he had a profuse hemoptysis and subsequent lung abscess. He recovered.

Dr. Kenneth Phelps: I would like to report the case of a child who had tonsillectomy under general anesthesia and later developed some trouble in the chest. It was several weeks before a diagnosis was made. The child had had a tooth knocked out and the trouble was due to this foreign body in the lung. It resulted in gangrene of the lung. Bronchoscopy did not save the child's life.

Dr. Moses Barron: I do not believe that it has yet been settled whether the lung infections following tonsillectomy are due to aspiration or are blood-borne. Pathologically it is difficult to decide. If the infection is blood-borne, why is it that the abscess is generally single and not multiple? It may be from a small mass of material in the tonsil. The difference between the two conditions is that in the case of a caseous gland which ruptures into a bronchus it keeps feeding the bronchus for a considerable period of time, while in the case of a tonsil it does this only momentarily. The caseous gland consists of a mass of necrotic tissue surrounded by a wall of tuberculous granulation tissue. This tuberculous granulation tissue contains the infecting material and will continue throwing off the bacilli long after the first rupture takes place. This is why one can get a bronchogenic pneumonia from a ruptured caseating lymph node. In the case of a tonsil, the condition is entirely different. The infecting material is given off only momentarily and abruptly. For that reason even if it spreads into the bronchi the abscess would be only a single one.

Dr. C. A. McKinlay: It is not so much to be wondered at that pulmonary and pleural suppurations occasionally follow tonsillectomy, but that they do not occur more frequently. For under either local or general anesthesia aspiration of material from the throat may occur unless, and even if, all possible precautions are taken in regard to the position of the patient, to the clearing of blood and mucus from the throat, and to the degree of tissue infiltration or of general anesthesia.

Dr. Moses Barron (in closing the meeting): I certainly wish to thank all the members of the Society for the honor and privilege of being president of this organization during the past year. It has been a distinct pleasure to occupy the office this year because of the support from all the members. I think that one of the great features of this organization is the fact that we come together here for sociability as well as for carrying on discussions in clinical medicine, and the trend has been that the better we are acquainted with one another the better we get along. The present group of officers is turning over the organization to the new officers in very good condition, both from the social and the financial standpoint. The financial report this evening quite surprised me. We undertook several things this year which involved considerable expenditure of money and yet we end the year with a good balance in our treasury. The excellent support from the members has resulted in properly fostering good fellowship as well as a better understanding of scientific medicine. I wish again to thank you for the confidence you had in me in electing me your President.

And now as to my paper this evening, since the discussion on Nephritis is rather a long one, and since it is nearly time to close the meeting, I think it would be better to postpone this paper until the next meeting. (Upon vote, a motion was carried that the paper by Dr. Barron on "Present Day Conception of Nephritis and Its Treatment" be carried over to the next meeting.)

The meeting adjourned.

H. B. Dornblaser, M.D., *Secretary.*

Meeting of March 12, 1931

The regular monthly meeting of the Minneapolis Clinical Club was held in the Hennepin County Medical Society Lounge on Thursday evening, March 12, 1931. The meeting was called to order about 7:15 by the President, Dr. F. H. K. Schaaf. There were 22 members present.

Following a short business meeting, the following scientific program was given.

Dr. William P. Herbst (by invitation) read a paper, illustrated with lantern slides, on "The Motility of the Upper Urinary Tract," and a study of the various functional disturbances of motility which open up a new field for the surgical treatment of various painful renal and urinary syndromes.

ABSTRACT OF DR. HERBST'S PAPER

Adequate drainage of the urinary tract, which is dependent mainly upon its motility, is, outside of excretion, the most important phase of the physiology of this tract. This tract has an inherent control mechanism which functions satisfactorily when severed from its connection with the central nervous system. This applies to its excretory function as well.

We have accurate knowledge of the action of certain drugs on the motility of the urinary tract gained from direct fluoroscopic observation. The usual urogram is a composite picture of multiple superimposed phases of motility.

Intravenous urography, when satisfactory, produces a picture not influenced by the over-distention nor incomplete filling incident to ureteral catheter injection. We have available a method of examination in pyeloscopy (fluoroscopic visualization of the motility of the urinary tract) that is relatively as satisfactory as fluoroscopic examination of the esophagus, stomach, small intestine, and colon, which makes possible the recognition of abnormal neurogenic functional mechanisms corresponding to such conditions as cardiospasm, spastic colon, Hirschsprung's disease, auricular fibrillation, and all types of obstructive pathology.

Eserine appears to offer relief in conditions of mild and transient pain due to certain of the functional disturbances in motility secondary to abnormal sympathetic influence.

There lie before us surgical procedures which promise much for the relief of very distressing types of renal and ureteral pain and various accompanying functional motility disturbances; also certain cases of chronic glomerular nephritis which are not making satisfactory progress under medical supervision and therapy. We have an explanation of the diametrically opposed views on the proper treatment of nephroptosis and the so-called ureteral strictures.

A number of slides were shown illustrating the mechanism of the motility of the urinary tract and also from a number of cases which were diagnosed as having definite functional motility disturbances of the upper urinary tract, with the diagnostic and therapeutic data.

Dr. Moses Barron then gave his Presidential Address, entitled, "The Present-day Conception of Nephritis."

ABSTRACT OF PRESIDENT'S ADDRESS

There is a great deal yet to be learned in regard to nephritis, but the recent work on this disease has clarified many of the complicated problems.

The term "nephritis" is used to designate that condition in which the glomeruli are quite generally involved throughout the kidney, the so-called glomerulonephritis. (Slides were shown to present the relationship between the diffuse glomerular nephritis and other kidney lesions.) In a general way the classification subdivided kidney affections into:

1. Benign albuminurias
2. Nephroses
3. Malignant hypertension
4. Senile arteriosclerotic kidney
5. Nephritides

Under the last subdivision was included, as a further subdivision, the diffuse glomerulo-nephritis.

The etiology of the disease is uncertain. According to Volhard the true hypertensions may be subdivided into the "red" hypertension or the so-called essential hypertension, and the "pale" hypertension of nephritis. His concept as to the pathogenesis of the latter is that there is a general systemic arteriolar and perhaps capillary constriction in which the glomerular capillaries and arterioles necessarily take part. The early change is a spasm of the arterioles with ischemia of the functional glomerular elements. The substance causing the constriction supposedly circulates in the blood, at first originating in the toxins of some infection in the throat or other parts of the body; later the constricting substance is elaborated in the kidney. According to Dr. Bell, the changes in the glomeruli are also brought about by an infection, but the glomerular changes are due to the direct effect of the bacteria and their toxins. He shows the presence of leukocytes and the proliferation of the endothelial cells as well as the epithelial cells in the glomeruli to substantiate his theory.

But whatever the original cause, the progress of the disease results in a gradual increase of fibrils and cellular elements and finally connective tissue in the glomeruli, with a gradual closing off of the capillaries and consequently a progressive ischemia. This finally goes on to kidney insufficiency.

The best tests for kidney insufficiency are the concentration and dilution tests. The former shows the functional ability of the kidney to concentrate the urine over and above the molecular concentration of the de-proteinized serum. In the advanced stages of kidney insufficiency, this ability is lost and the urine maintains a constant specific gravity of 1.010, which is that of the de-proteinized serum. This is known as isothenuria. The normal kidney can concentrate at least to a minimum of 1.025, and usually higher. The importance of this ability to concentrate lies in the fact that the present-day concept of renal function (Cushney, Richards) assumes that the urine as elaborated in the glomerular spaces is a simple filtrate of de-proteinized serum. This urine, serum minus the colloids, is concentrated in passing through the convoluted tubules by the resorption of water (and certain threshold substances such as glucose). This ability to concentrate is apparently decreased through the progressive loss of the functioning ability of an increasing number of the secretory elements—the glomeruli with their tubules.

The next stage of kidney insufficiency is when it is unable to dilute. The normal kidney can dilute the urine, following the ingestion of 1,000 to 1,500 c.c. of water, to as low as 1.002 or even 1.001. Later the products of metabolism may be retained in the blood serum as is revealed by the blood chemistry.

The edema which may accompany the nephritis is not directly renal in origin, but may be considered as extra-renal.

The acute stage of nephritis may go on to recovery with complete restitution, or to death either from cardiac decompensation, uremia, or secondary infections. Some cases go on to chronicity and then may become either subacute, subchronic, chronic, or recurrent. Recovery after one year's duration of the nephritis is rare; after two years, practically never.

The treatment during the acute stages is to limit the fluid intake according to the patient's ability to excrete, restricting the protein intake to 20 or 40 grams a day, and to give a high carbohydrate diet rich in fruits and vegetables, salt intake to be limited to obviate edema. The three-day starvation diet of Volhard may be tried, followed by his so-called "Wasserstoss." One must be careful in using the latter procedure. Diuretics are of very little importance.

A number of charts were shown to illustrate the normal structure of the glomerulus as well as the pathological one in nephritis. A large series of very beautiful photomicrographs taken from glomerular nephritis in various stages were shown. These were obtained through the kindness of Dr. E. T. Bell, of the Department of Pathology of the University of Minnesota.

There was no discussion of either paper.

The meeting adjourned.

H. Bright Dornblaser, M.D., *Secretary.*

"A train of thought may die away without any recognizable external result of any kind. When Archimedes invented his test of specific gravity, he ran into the street and shouted; but in the preceding twelve months he must have done a good deal of thinking that left his muscles passive."—*Graham Wallas.*

PROGRESS

Abstracts to be submitted to Section Supervisors.

Members are urged to abstract valuable articles which they run across in their reading and send the abstracts to the physicians in charge of the respective sections. In order to avoid duplication it would be well to communicate with one of the section supervisors before the article is abstracted.

MYOPIA FROM THE POINT OF VIEW OF HEREDITY. Ejler Holm, Acta Ophthalmologica, Vol. III, Fasc. 4, Pages 335-347. It has long been known that heredity plays an important rôle in the etiology of myopia. In order to determine the relationship of heredity to myopia, Jablonski in 1922 studied the difference of refraction in twins of the same sex (some were unioval, the others were not). In the unioval twins in whom the hereditary influences could be considered equal, the difference of refraction was not more than two diopters. However, this does not indicate that external influences can not affect refraction more than two diopters, as his material was too limited. Only two cases of myopia were included in Jablonski's work.

Tscherning first pointed out that there was a possibility of two kinds of myopia. The first depends on near work and does not exceed six diopters; the second depends on hereditary factors and is over nine diopters. Reading myopia, however, is probably dependent on hereditary factors which are present in non-readers to an equal extent as in readers, but which are manifested more frequently in the readers.

Jablonski in his study of pedigree arrived at the conclusion that myopia is a recessive hereditary affection. His work was done on patients who were largely non-readers, therefore his results cannot be considered as a support of the assumption that myopia is always a purely hereditary affection independent of near work and other external conditions.

Very little attention has been given to reading-myopia from the standpoint of heredity. In a series of case reports the author attempts to show that reading-myopia depends upon heredity. The author believes that the hereditary factors for reading-myopia as well as the other type not dependent on reading should be the same. There may be a whole series of multiple specific hereditary factors for myopia so that a single one of them may be able to produce myopia under external conditions which are favorable to its development; while, if a greater number are present, myopia may occur irrespective of external circumstances. Thus, myopia occurs more frequently in families whose members read much and less frequently in families whose members do not read much.

James Brusegard.

USE OF INSULIN IN POST-OPERATIVE MASTOIDITIS. Matthew S. Ersner, M.D., and Joel J. Pressman, M.D. (Ann. of Otol., Rhinol. and Otolaryngol., Volume XXXIX, December, 1930, Number 4). This article discusses briefly the rationale and the results of the use of insulin in the post-operative treatment of acute mastoiditis. In this series of cases none were diabetic, but all showed a greater or lesser degree of debilitation, with poor tissue repair and a prolonged period of healing. Poor appetite and nutrition were invariably present. It is the belief of the authors that graded administration of insulin greatly improves metabolism, increases appetite and nutrition, and, in this way, breaks into the vicious circle of debility and prolonged suppuration.

After the use of insulin, without exception there was a marked increase in appetitie, with gain in weight and well-being. The wound granulations took on a more healthy appearance and repair went forward at a normal and satisfactory gait.

Children were given single daily doses, one-half hour before lunch, the initial dose being 3 units, increased rapidly to 5 or more. They believe the diet should lean more toward fats than carbohydrates, but an ample amount of the latter is absolutely essential.

In this series treatment was not started until the seventh post-operative week, at which time there was active suppuration and little attempt at healing. Drainage decreased rapidly and healing began, hand in hand with the improvement in the general condition.

Their conclusions are as follows:

1. Many post-operative cases of acute mastoiditis are in a generally debilitated state from prolonged illness and operative procedure.
2. This state of debilitation often prevents the proper healing of wounds.
3. Insulin injections have a decidedly tonic effect upon such cases.
4. Increased appetite, gain in weight and improvement in general health result in increased rapidity in healing.

M. W. Wheeler.

THE MAXILLARY ANTRA AS FOCI OF INFECTION. C. B. Williams, M.D., Mineral Wells, Texas (Ann. of Otol., Rhinol. and Laryngol., Volume XXXIX, December, 1930, No. 4). The author first states the objects of his paper, which are twofold:

1. To present evidence from recent literature and case reports from our records supporting the idea that maxillary antra commonly act as foci of infection.
2. To stress the importance of careful routine examinations of these regions when searching for the cause of conditions which are generally supposed to be due to such foci.

RECENT LITERATURE

A consideration of recent literature reveals that quite an advancement has been made within the past few years in our method for determining diseased conditions of the maxillary antra and that a pronounced tendency toward conservative treatment of all the naasl sinuses, except possibly the antra, is quite apparent.

The author next gives a group of excerpts and notations from recent articles which give an idea of the many and varied diseased conditions which are being attributed to infected sinuses in general. In this group are case reports covering the following diseased conditions: Myocarditis, chronic bronchitis and perennial asthma, retro-bulbar neuritis, chorea, vertigo, headache, cough, profuse nasal discharge, eye disturbances, anemia, dizziness, constant cold in nose and discharge, foul breath, headaches and trifacial neuralgia.

The author next reports cases of his own attributed to antral infection which include the following conditions: 1. Persistent corneal ulcer. 2. Facial paralysis. 3. Tic douloureux. 4. Acute arthritis.

The author comments that infected antra can be and often are responsible for these different diseased conditions, and that it is certainly important that we make it our habit to routinely investigate the antra in every case that comes under our care; that patience and skill are often required to arrive at a fair conclusion as to whether an antrum is infected; that allergy, through blocking, should always be kept in mind.

He summarizes by stating that from different sources in recent literature and his personal experience of over 30 years, evidence is gleaned that any diseased condition which may arise from a focus of infection anywhere in the body can and often does arise from diseased maxillary sinuses. This being true, the antra should be routinely investigated when searching for foci of infection.

The article is concluded with the mention of a recent article by E. M. Anderson (Anderson, E. M., Jour. A. M. A., June 14, 1930, p. 1889) of Rochester, Minn. The author states, "I mention this article only to express my hearty disagreement with its general import. Under 'Summary and Conclusions' among other things Anderson states that 'suppurative sinusitis may be a focus of infection on rare occasions.' I do not feel that this view by any means expresses the consensus of opinion of present-day otolaryngologists."

Lucian G. Culver.

MEDICINE

TUBERCULOSIS ABSTRACTS*

What rôle does calcium play in the healing of tuberculous lesions? Does the deposit of calcium hasten the reparative process or does it but replace destroyed tissue? No other mineral element has been so thoroughly investigated in tuberculosis research as calcium. Attempts to influence the course of tuberculosis by the therapeutic use of calcium have repeatedly failed. But more recent knowledge about nutrition and heliotherapy has revived interest in the subject. Calcium metabolism is undoubtedly influenced by vitamins and by certain rays of the solar spectrum. A general review of the calcium question should be helpful in evaluating the claims and theories of recent writers. The following notes are derived from the November, 1930, *American Review of Tuberculosis*, in an abstract of a paper by R. Monceaux in the Revue Belge de la Tuberculose.

CALCIUM EXCHANGE IN PULMONARY TUBERCULOSIS

Boyer, in 1869, declared that the lung undergoes a decalcification in phthisis, but it is chiefly to Ferrier that latterly accepted theories are to be credited. Ferrier's experiments were crude and his evidence was not convincing, but he added other arguments that had to do with the relation between dental caries and bony demineralization, the calcium reserve, and other suggestive observations. Most French authors contend that decalcification begins in the early stages of tuberculosis and disappears in advanced cases. This they determined simply by estimating the amount of calcium excreted in the urine. Robin gives the normal urine calcium as 0.281 gms. per day.

COMMENT ON DECALCIFICATION THEORY

To consider only the degree of calcuria is very misleading for it may vary from 0.16 to 0.69 gms. on an identical regimen. In fact, most of the calcium is ordinarily excreted in the feces. The only really scientific method of estimate is to determine the calcium balance or relation between total intake and output. This has been done in tuberculous patients, at rest and on a measured ration, and a negative balance was found in certain patients in whom active disease caused wasting. In these cases, a dose of 2 gms. calcium oxide per day was necessary to compensate the loss. Except for these conditions, tuberculous persons behaved about normally and consumed daily about 1.5 gms. calcium oxide. Hence, it was concluded that decalcification is not a specific characteristic of tuberculosis but is associated only with denutrition. One investigator even found positive balances in a number of tuberculous persons.

Ferrier declared that dental decalcification went hand in hand with body decalcification. Others have been unable to confirm this, and Villemin pointed out that in rachitic children dental lesions were rare.

Barkus was unable to determine any loss or any increase of calcium as cure occurred and in guinea-pig experimental tuberculosis could not demonstrate any diminution of calcium. Others even found an increase in animal necropsies, and some have shown that the calcium content of organs varies with the physiological state.

CALCIUM IN THE BLOOD

Recent studies have been made on the blood calcium. Tuberculosis *per se* causes no lowering of blood calcium. Hemoptysic patients with prolonged coagulation time showed slightly lower concentrations but the differences were slight. The normal variations are from 9.22 mgm. per 100 c.c. serum to 10.78 mgm. From 120 to 130 mgm. per litre were found even in cavity and bronchopneumonic cases. The tuberculous blood is not impoverished in calcium. Moreover, variations, when they exist, are dependent on cachexia and alimentary insufficiency.

RECALCIFICATION

In spite of these objections, the dogma has been reiterated that the great curative principle in tuberculosis is recalcification. This is carried out (1) by administering calcium phosphate and other salts and (2) by instituting a diet regimen. The only demonstrable advantage of calcium medication is that it may act favorably on the stomach, which often in the tuberculous shows hyperchlorhydria. Calcium lactate given by mouth does not increase the blood calcium, nor will a calcium-rich dietary increase tissue calcium. In fact, in the tuberculous, calcium chloride or lactate may even increase calcium loss, especially the chloride. The glycerophosphates and carbonates are not assimilated at all and even increase calcium loss. Phosphorus and calcium have a certain optimum relation, realized in the tuberculous when there is a slight excess of calcium. If this is exceeded, there is a tendency to the formation of insoluble calcium phopshate, which is eliminated by the intestine—therapeutic decalcification. Calcium therapy might be useful when there is insufficient alimentary calcium, as in Germany during the War, but metabolic disorders cannot be combated; that is, the organism cannot be made to fix calcium. Superfluous quantities are rapidly precipitated in the tissues for the blood is normally physiologically saturated.

FIXATION OF CALCIUM

It was believed that the addition of adrenalin would solve the problem, and two workers diminished calcuria under this regimen. However, these results have been questioned and it has been shown that there is always a corresponding intestinal debit. Solar ray, ultra-violet radiation, and Vitamin A have been used but without effect. In rickets, only the ultra-violet rays and cod liver oil containing Vitamin A protected animals, but this condition differs essentially from tuberculosis.

*Reprinted from Tuberculosis Abstracts, a review for physicians issued monthly by the National Tuberculosis Association. February, 1931, Vol. IV, No. 2.

CALCIFICATION OF TUBERCLES

Calcium deposits in tubercles have been accepted as obvious proof that calcium plays a defensive rôle by walling off bacilli. However, calcium salts are only deposited in necrotic tissue. Calcium does not precede nor favor cicatrization of lesions and probably does not even arrest the progress of lesions. It is much more probable that calcification follows rather than effects a cure. In bovine tuberculosis, large quantities of calcium are deposited in and about progressive lesions. Also, bony tissue offers no special resistance to tuberculous infection.

Individuals who breathe lime dust all day possess a special resistance to tuberculosis. This is incontestable. But its action may well be a simple mechanical one, simulating sclerosis.

Calcium salts do not inhibit the development of the tubercle bacillus; on the contrary, they often favor growth on culture media. Neither has any favorable effect been noted in tuberculous animals.

CONCLUSIONS

If there is no decalcification, still the tuberculous need a little more lime than normal persons to maintain a favorable balance. Calcium may stimulate phagocytosis and certain other favorable reactions. However, intensive calcium therapy, on the basis of the foregoing work, must be rejected as useless. Nature furnishes abundant calcium, especially in water, milk, eggs, and legumes. The best alimentary medium is milk, of which 0.5 litre per day, with leguminous purees or eggs, suffices. Articles which tend to precipitate calcium in the form of oxalates—rhubarb, sorrel, cocoa, endive—should be avoided. If in the presence of food rich in calcium it is not assimilated, the organism is at fault physiologically. This is often the case in tuberculosis, especially when oxidation is impaired, with a resultant tendency to humoral acidity. In such cases, phosphoric acid may be given, which indirectly favors retention of calcium. The biphosphates and lactophosphates can also be used.

Basic Feeding in Tuberculosis

Mayer and Kugelman, in a preliminary report on "Basic (Vitamin) Feeding in Tuberculosis," Journal of the American Medical Association, December 14, 1929, attempt to evaluate the special dietary regimen for tuberculous patients advocated by Sauerbruch and Gerson. They declare that dogmatic statements are not not yet warranted but admit that the favorable results observed in about one-third of the patients studied may perhaps be attributed to the effect of the dietary.

The authors maintain that the special dietary is an alkali-forming one and not acid-forming as the Germans contend. Experimental studies on the effect of acid and base-forming dietaries in rats show that animals on the base-forming dietary throve to a maximum degree, grew rapidly, and were more active than those on the acid-forming diet. Similar studies on patients showed that the acid-base equilibrium shifted toward the basic side on base-forming diet. They believed that the inorganic constituents and the vitamins are the favorable factors and that the vitamins are the more important. The absorption and utilization of minerals depend on the vitamins present in the alimentary tract.

DEVELOPMENT IN THE PROBLEM OF ARTHRITIS: Ralph Pemberton, Philadelphia (Jour. of the A. M. A., January 3, 1931). The medical profession has not seriously regarded the problem of arthritis even though it involves a large percentage of the population. However, the profession is coming to recognize the two main types of the disease, namely the atrophic and hypertrophic, and to give varying emphasis to the etiologic and therapeutic factors bearing upon them. In Europe today there is a large movement for the study and treatment of this disease, and coöperating with this movement is the American Committee for the Control of Rheumatism. Dr. Pemberton stresses the fact that arthritis is a systemic disease; that the background for it is often hereditary; that certain types of persons are most frequently attacked; and that there are prodromes that enable one to recognize susceptible individuals and often prevent the disease, especially perhaps in the atrophic type. The problem of infection, of which so much has been heard in recent years, seems to be in many cases only the precipitating agent, and sometimes rather frequently focal infection is the result of the background rather than the cause of it.

Physicians are paying more attention to the question of a disturbance of the finer blood supply to the various parts of the body, and which bears a definite relationship to both types of arthritis. Definite proof of this conclusion is to be found in studies of the blood gases, study of the rapidity with which the circulation in arthritic patients takes care of substances absorbed into it from the digestive tract, and in the study of the blood count in the blood first issuing from the capillary beds at the periphery in the arthritic subject. Studies of the surface temperature of arthritics show that they have a lower peripheral temperature because of the decreased blood flow in the tissues concerned. The capillary bed appears to be immobile and in a state resembling vasoconstriction. This is probably the explanation of the added discomfort expressed by arthritic patients from changes in the weather.

He again stresses the fact that it is a variety of factors which contribute to bring about the disease and that no agency or organism is recognized as the single cause of it; and that attacking this problem with any drug or any vaccine alone is too often like firing at the head above the ramparts instead of the fortification itself. It is the opinion of most of the American Committee for the control of this disease that the physician must focus his attention on the disease as a whole rather than focusing it on any one factor, whether it be mechanical, bacteriologic or nutritional.

Even irregular practitioners have begun to treat this disease with a breadth of view that some of the leaders of medicine do not entertain, and "is the medical profession to allow to be repeated here the experience in the field of physical therapy, in which the laymen and the quacks almost alone kept alive therapeutic principles rediscovered fifty years later by orthodox medicine?"

Richard Bardon, M.D.

PEDIATRICS

FACTORS INVOLVED IN COMBATING THE "HUNGER STRIKE" IN CHILDREN: William Palmer Lucas, M.D., and Helen Brenton Pryor, M.D., San Francisco (Amer. Jour. of Diseases of Children, Vol. 41, No. 2, February, 1931). The main complaint of anorexia presented by the 110 children was accompanied by constipation in forty-six cases and by indigestion, abdominal pain or vomiting in eighteen cases; thirty-six suffered from styes, boils and frequent infections; sixty-two were underweight, and forty-one of these were described as overactive or highstrung, easily fatigued and irritable. Extremely high rates of basal metabolism accompany and possibly explain the nervous type of overactivity which results in this fatigue and irritability. Psychologic examinations of a number of this group indicated intelligence higher than the average.

Enforcing abundant rest is effective in overcoming problems of behavior as well as important in the treatment for anorexia. Our regimen of rest provided for breakfast in bed, getting up at 10 A. M., being out of doors in the sunshine if possible until noon, a nap from 1 to 3 P. M. and going to bed at 7 P. M.

Functional versus organic types of anorexia have been discussed by Bartlett, Schlutz, Carlson, and others. The deleterious effect on the appetite of a high proportion of fat in the diet has been well described by Aldrich, who said that all foods rich in fat pass out of the stomach slowly, and that "The stomach tends to be low and to empty slowly in all patients with poor muscular development, especially in those of slender type." Poor appetite in itself causes a decrease in the secretion of gastric juice, and therefore may delay the digestion and emptying time of the stomach.

McLean and Fales have pointed out that "the thin underweight child requires considerably more food than the normal allowance." Conversely, the fat child requires less than the normal because of lowered basal metabolism, and because of diminished needs for body building. The author's experience leads him to agree with Garland, Aldrich and others that milk should be eliminated from the diet or be greatly reduced in amount, as a first step in dealing with anorexia. The author substituted a quart of fruit juices for the usually accepted quart of milk.

In the 110 cases of anorexia reported, the author has had good results after from six weeks to three months on diets of low residue, low fat and high vitamin content, or on diets of low fat, low starch and high vitamin content, combined with a regimen of rest and special therapy indicated.

Body measurements established the fact that 82 per cent of 110 children complaining of anorexia, had the linear type of build.

Obstinate constipation had a high correlation with poor nutrition in the linear type in this series.

Diets high in fat content commonly fed to underweight children are contraindicated for subjects of the linear type.

Children of the linear type should be given diets with a low fat content.

The substitution of one quart of fruit juices for the one quart of milk a day usually prescribed has a stimulating effect on the appetite.

A diet of low residue successfully combats persistent constipation associated with mild distention of the colon.

R. N. Andrews, M.D.

LOW FAT HIGH STARCH EVAPORATED MILK FEEDING FOR THE MARASMIC BABY. John Howell West, M.D., Easton, Pa. Arch. of Ped., Vol. XLVIII, No. 3, March, 1931.

The most difficult feeding problems encountered by the pediatrician in the care of the artificially nurtured infant are probably found in the so-called marasmic group. These babies suffer from a severe form of malnutrition, designated by Finkelstein as the state of decomposition.

Nobecourt thinks that there is marked intolerance for fat, while Grulee suspects that the sugar element is at fault, as many of these babies have been fed on sweetened condensed milk. Pacchioni believes that there is a deficient functional activity of the body cells themselves which prevents adequate assimilation. Finkelstein, in 1922, advanced the theory that cow's milk causes an injury to the intermediary metabolism. Suffice to say that there is an apparent intolerance for fat and soluble carbohydrates with an almost complete lack of the assimilative function.

His feeding problem, it appears, is to supply a readily digestible high caloric type of feeding with a low fat and sugar content. Modified unsweetened evaporated milk furnishes such a food. Evaporated milk is practically a double strength whole cow's milk. Its virtue lies in the homogenization of its fat with resulting breaking up of the large fat globules of plain cow's milk into tiny droplets resembling the fat of human milk. A very important argument in favor of this type of feeding, and one not sufficiently stressed, is the fact that evaporated milk may be fed and digested in much stronger dilutions than plain cow's milk, and so provides the additional calories frequently required to put the baby "over the top" nutritionally. By dilution the fat and soluble carbohydrate content may be reduced to the desired low percentage, and the caloric value may be increased to any desired point by the addition of protein in the form of calcium caseinate and starch in the form of baked wheat or barley flour.

The marasmic infant is frequently started upon a formula containing four ounces of evaporated milk in a 32-ounce formula. In order to increase the calories of the mixture, however, as well as the protein percentage, one ounce (three heaping tablespoonfuls) of calcium caseinate is added which increases the protein content to 3.8 per cent., approximating that of Finkelstein's original protein milk. The carbohydrate is increased four and one-half per cent by adding one and one-half ounces (three rounded tablespoonfuls) of baked wheat or barley flour. As the baby thrives, the fat is cautiously increased by adding one-half ounce of milk and removing a similar quantity of water from the mixture. The sugar of choice has been lactose because of its pronounced effectiveness in increasing calcium absorption, and also for the reason that it favors the development of excellent tissue turgor. As the weight curve goes up, one-half ounce (one rounded tablespoonful, 60 calories) of lactose may be added, removing the same amount of flour. As the tolerance for sugar improves, the lactose is gradually increased to one and one-half ounces (three rounded tablespoonfuls). The resistance to infection while on this feeding plan appeared excellent.

The marasmic baby is usually intolerant to fats and sugars, and for this reason does not do well on the ordinary raw or cooked cow's milk dilutions with soluble carbohydrate additions. A very digestible high caloric type of feeding is essential. The easily digested unsweetened evaporated milk with additions of calcium caseinate and starch has been found to satisfactorily fulfill these requirements.

R. N. Andrews, M.D.

ROENTGENOGRAPHIC RE-EXAMINATION OF CHESTS OF CHILDREN AFTER MEASLES.

Jerome L. Kohn, M.D., and Henry Kosransky, M.D. (Amer. Jour Dis. of Children, March, 1931). Previous report had covered roentgenograms of chest in 130 children during measles eruption. Shadows suggesting pulmonic infiltration were present in 61 per cent, before or during height of the eruption.

In re-examination in six to ten months, the investigation covered fifty-six of the above mentioned cases. Thirty-two were under 4 years and twenty-four over 4 years of age. Report included an interval history, physical examination and roentgenogram of chest.

Of the fifty-six children re-examined thirty-four had shadows of infiltration during measles eruption. Of these only eight now showed slight accentuation of the basal markings, a condition not indicative of permanent change.

"It would seem, therefore, . . . that if the child recovers from a severe case of measles, complicated by extensive pulmonary involvement, the chances of residual changes in the lungs, such as chronic fibrosis or bronchiectasis, is slight."

Pleural involvement was fairly frequent—interlobar pleuritis being noted in 26 per cent of the cases. Of these, about 53 per cent remained as interlobar shadows at the time of re-examination, and were found mostly in those that previously had pulmonic infiltration in the upper or mid lobes. Thickening of the parietal pleural commonly noted in the axillary region persisted in 16 cases to the time of re-examination.

Seventy per cent showed large homogeneous hilar shadows during eruption. The size and density of these shadows had diminished in thirty-nine of the fifty-six cases on re-examination.

In only one case of the series was an old tuberculosis aggravated by the measles infection.

The authors regard the frequency of pleural involvement to be especially worthy of comment.

J. G. Lamont, M.D.

TETANY, GENERALIZED EDEMA AND CEREBRAL COMPRESSION IN THE NEW-BORN.

W. Ray Shannon, M.D., St. Paul, Minn (Arch. of Ped., Vol. XLVIII, No. 3, March, 1931). Tetany, to be accurately understood, must be thought of primarily as a symptom-complex and not as a disease entity. Most important as a means of identifying the condition are the motor symptoms of which the widely spoken of carpopedal is the most common.

A decrease in the total calcium content of the blood is noted in all of those diseases which result in a lowering of the plasma protein level. However, in these conditions the decrease in calcium content is at the expense of the bound fraction, and tetany does not result. A decrease in the total calcium level occurs in insufficiency of the parathyroid mechanism, whether postoperative or idopathic. In this case, both the bound and the unbound fractions are decreased and tetany results, if the calcium level be sufficiently low. The idiopathic hypoparathyroid form of tetany has a definite hereditary basis. The function of calcium is that of neutralizing certain toxic substances whose poisonous effects show themselves in the absence of sufficient calcium by the signs of nervous irritability common to tetany.

The essential characteristics of the picture are spastic contractures of the upper and lower extremities, positive Chvostek's and Trousseau's phenomena, hyperactive reflexes with frequent ankle clonus, irregular clonic spasms of the facial and skeletal musculature, and increased electrical excitability.

In considering cases of infantile tetany one cannot but be struck by the fact that there is a group of three major symptom-complexes presented, namely, peripheral excitability, generalized edema, and cerebral compression.

Etiologically, it is reasonable to assume that a disturbance of the calcium metabolism is at fault, in view of the dramatic response to calcium therapy. In a case of this nature, developing in the presence of a low serum calcium, one is justified in presuming that a hypoparathyroidism is underlying, though such parathyroid deficiency must be assumed, in this as in idiopathic tetany in general, to be functional in nature. Whatever the minute mechanism may be, one is at least justified in assuming that a very delicate adjustment of chemical processes is concerned and that calcium constitutes a very important factor in that adjustment.

Tetany is to be thought of as a symptom-complex and not as a disease, due to a deficiency more qualitative than quantitative in the calcium content of the blood and tissues. It is contended that tetany is in reality of frequent occurrence in the new-born infant. Therapy consists of calcium feeding, the administration of parathyroid extract, and the use of viosterol.

It is, therefore, further contended that, standing in a causal relationship with the tetany which is of frequent occurrence in the new-born, there exist two groups of symptoms dependent also upon the deficiency in calcium, namely, general subcutaneous edema and edema of the brain, and that the three groups constitute a triad dependent primarily upon a qualitative or quantitative deficiency in the calcium metabolism of the new-born.

R. N. Andrews, M.D.

SURGERY

THE TREATMENT OF EPICONDYLITIS HUMERI (Tennis Elbow): Prof. Dr. C. Mau, of Kiel (Der Chirurg., Vol. III, No. 1, January 1, 1931, p. 5). Reviewing briefly the history of the description of this disease, as well as the possible etiological factors connected with it, the author is of the opinion that it is a circumscribed chronic periostitis of the antero-lateral surface of the external condyle of the humerus, occasionally due to a direct trauma, but in the majority of cases due to abnormally firm gripping of the hand in certain occupations, which causes a stong muscle pull of the extensor muscles attached to the condyle (supinator longus, extensor carpi radialis longus and brevis, extensor digitoris communis, extensor digitoris minimi digiti, extensor carpi ulnaris). These muscle insertions unite in a tendinous sheath or aponeurosis, which is attached to the periosteum at this point. Occasionally one gets a positive X-ray finding, showing periosteal thickening, in a view taken in a slightly oblique direction. This condition is found in occupations where a hammer is used with a twisting motion, such as in riveting, or in certain sports, such as tennis, fencing, and golfing.

While this condition is in itself not dangerous, yet it is apt to be very chronic and quite resistant to treatment, especially the usual conservative treatment, such as local applications, electric treatment, and baking. Of the conservative treatment, best results are obtained by diathermy. Massage is not only useless, but often harmful. Local injections do not give lasting benefit. Besides diathermy, the best conservative treatment consists in absolute rest of hand and elbow joints for a number of weeks, especially in a cast, holding the hand in dorsal extension with a full extension of the metacarpophalangeal joints, keeping the elbow quiet with a plaster-of-Paris cast. While beneficial in cases, yet it means inability to fill one's occupation, and also interferes with the numerous personal gestures needed in routine daily life.

It was Franke who suggested to chisel off the epicondyle, thus relieving the strain; but a better procedure, and the one which the author recommends highly, is the suggestion of Hohmann, who, at the Orthopedic Congress in Cologne in 1926, suggested nicking the tendinous insertion at the epicondyle under local anesthesia. The technic of the operation is simple. Under local anesthesia a curving incision is made over the epicondyle, and is made about 2 cm. in length. One isolates the aponeurosis of the extensor insertions, and nicks the same with a knife for a distance of 1 to 2 cm., immediately adjacent to the bone. In this way the whole extensor insertion at this point is relieved of tension. Without using deep sutures, a superficial skin suture is employed, and the arm is carried at right angled flexion at the elbow for a period of eight to ten days, using a simple splint. The hand can be left free for lighter manipulations. At the end of eight or ten days the sutures are removed, and soon routine use of the hand and elbow is begun.

There is a report of four cases given in detail, and reference is made to another twelve cases operated by Hohmann, all with excellent results. There is one illustration in this article, showing the skin incision and the exact point of nicking the tendon sheath.

A. E. Sohmer, M.D.

THERAPEUTIC PULMONARY COLLAPSE BY ALCOHOLIZATION OF PHRENIC NERVE. F. Cordrey and P. Philaredau, La Presse Medicale, February 31, 1931, Number 15, Page 271. These authors review the indications for pulmonary collapse in the treatment of certain lung conditions, and refer especially to phrenicectomy or removal of the phrenic nerve for immobilization of diaphragm. Because in certain cases it might be advisable to re-establish diaphragmatic function, some surgeons, instead of removing part of the nerve, practiced mere phrenicotomy or section of the nerve; but the re-establishment of the course of the nerve is difficult because of the location of the nerve, as well as the small size of its ends; and also because of the difficulty of exposing these ends in scar tissue and reuniting them.

In order to get complete abeyance of the phrenic nerve for a limited time, with a possibility of restoring its function, the authors have been using alcoholic injections into the nerves, similar to those that are used in trifacial neuralgia. They state that there are two possible ways of doing this—either by the closed method, or by the open method; because of the possibility of damage to the tissues, especially the pleura, they advise exposing the nerve in similar manner to that when phrenicectomy is done. One c.c. of alcohol is injected into the nerve. In a series of cases mentioned, the authors have used this method and they have found it satisfactory—thus getting immediate immobilization of the diaphragm on one or both sides, with resumption of function after a period of one to three years.

A. E. Sohmer, M.D.

BOOK REVIEWS

Books listed here become the property of the Ramsey and Hennepin County Medical libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

BOOKS RECEIVED FOR REVIEW

General Surgery (Practical Medicine Series). Edited by Evarts A. Graham, A.B., M.D., Professor of Surgery, Washington University School of Medicine, Saint Louis, Missouri. 848 pages. Illus. Price, $3.00. Chicago: The Year Book Publishers, 1930.

Easier Motherhood. Constance L. Todd. 199 pages. New York: The John Day Company, 1930.

The Letters of Dr. Betterman. Charles Elton Blanchard, M.D. 157 pages. Price, $1.00. Youngstown, Ohio: Medical Success Press, 1931.

Roentgen Interpretation. George W. Holmes, M.D., Roentgenologist to Massachusetts General Hospital and Assistant Professor of Roentgenology, Harvard Medical School, and Howard E. Ruggles, M.D., Roentgenologist to University of California Hospital and Clinical Professor of Roentgenology, University of California Medical School. 339 pages. Illus. Price, $5.00. Philadelphia: Lea & Febiger, 1931.

Crippled Children. Earl D. McBride, B.S., M.D., F.A.C.S., Instructor in Orthopedic Surgery, University of Oklahoma, etc. 280 pages. Illus. Price, $3.50. Saint Louis: C. V. Mosby Company, 1931.

Prenatal Care. Bureau Publication No. 4, United States Department of Labor, Children's Bureau. 71 pages. Illus. Price, 10 cents. United States Government Printing Office, Washington, 1930.

MODERN METHODS OF TREATMENT. By Logan Clendening, M.D., professor of clinical medicine, University of Kansas. Cloth. Price $10. Pp. 820. Fourth Edition. St. Louis: The C. V. Mosby Company, 1931.

This book first appeared in 1924. The second and third editions followed in 1928 and 1929. The author's clarity in describing methods of procedure, and the ready usability of the material explain much of the generous acceptance of the work; the charm of historical background and personal commentary which makes his "The Human Body" such fascinating reading are by no means absent from this volume. In his preface the author makes a remark of the type which lends a peculiar flavor to all his work: "Several mistakes (e.i. occurring in the third edition) which, as Horace Walpole said, indicated that it was the work of a gentleman rather than a mere scholar, have been corrected."

Other than a careful revision, the inclusion of certain new material chiefly distinguishes this edition from the preceding one. The author discusses these changes in his preface as follows: "I have not endeavored to add every suggested change in therapy that has developed since the last edition. My inclusions have been conditioned both by the limitations of my experience and by my judgment as to what methods are firmly established and buttressed by scientific evidence. Harington's work on the chemistry of the thyroid principle, the use of desiccated swine stomach in pernicious anemia, salyrgan, postural rest in tuberculosis as advocated by Webb, Calmette's B.C.G. tuberculin, undulant fever, ethylene and the use of parathyroid hormone in Paget's disease, and hyperparathyroidism have all been described. The sections on myxedema, diabetic coma, diet in tuberculosis, cisterna puncture, and infantile paralysis have been rewritten for this edition."

E. C. Hartley, M.D.

MODERN MEDICINE. Osler and McCrae. Third edition. Volume VI. 964 pages. Price $9.00. Philadelphia: Lea & Febiger, 1928.

Volume VI of Osler and McCrae's Modern Medicine deals with the Diseases of the Nervous System and Diseases and Abnormalities of the Mind. As a text on these subjects it is unusually complete, simply written, and very readable. With a list of twenty contributors, the names of whom would be an asset to any volume of this kind, this book gives an accurate account of the established facts as well as the most generally accepted theories and opinions in Neurology and Psychiatry.

Joel C. Hultkrans, M.D.

ANTE-NATAL CARE. W. F. T. Haultain and E. Chalmers Fahmy. 2nd edition. 127 pp. Price, $2.25. New York: William Wood & Co., 1931.

This is a concise outline of the various conditions encountered during pregnancy, together with a very brief outline of treatment and management. The first chapter describes the equipment and routine procedures of the prenatal clinic of the Royal Maternity and Simpson Memorial Hospital of Edinburgh.

Therapeutic measures are mentioned, but there is very little detail. The text probably would be more valuable to the student than to the practitioner.

L. R. Critchfield, M.D.

LABORATORY PEDIATRICS (Clinical Pediatrics, Volume XX). John D. Lyttle, A.B., M.D. Supervising Editor, Royal Storrs Haynes, Ph.B., M.D. 189 pages with contents, 31 illustrations, references and index. Price: $85.00 per set of 20 volumes and general index. Sold only in sets. New York, London: D. Appleton & Co., 1930.

The author has beautifully accomplished his purpose as expressed in the preface. There is a wealth of very fine material, tables and valuable laboratory data. One fancies a general practitioner would like, in a book so enlightening and stimulating, less of the clinical or the same amount of the clinical with more of the underlying bases of the procedures in the various laboratory tests and more complete and specific references in the bibliography. Also he would wish that still more of the methods be given.

Much food for thought and stimulus to research are embodied throughout. One feels like saying as the pages are read "whoa" and call a halt to the aeroplane view and automobile racer and to ask a pause for more detail here and there. It is just too fine a book to leave out such desired material.

The book is to be welcomed and most highly recommended, with congratulations and thanks to the author.

LILLIAN L. NYE, M.D.

COMPOSITE INDEX AND CUMULATIVE SUPPLEMENT (Clinical Pediatrics, Volume XXI). 385 pages, with contents, composite index, 5 illustrations and references. Price: $85.00 per set of 20 volumes and general index. Sold only in sets. New York, London: D. Appleton & Co., 1930.

While primarily intended for the general practitioner this volume is to be recommended to the pediatrician and obstetrician.

The Composite Index constitutes the first part of this volume and is very complete and valuable. The second part, the Cumulative Supplement, covers the development since the publication of the original manuscripts. Drs. Grulee and Bonar discuss in two sections, "The Newborn—Physiology and Care" and "The Newborn—Diseases and Abnormalities" with a bibliography; Dr. Veeder contributes "Preventive Pediatrics"; Dr. Neff, "Diseases of the Digestive System"; Drs. Lucas and Washburn, "Diseases of the Blood and Blood-Building Organs."

May the supplements continue to follow! May there be frequent revisions!

LILLIAN L. NYE, M.D.

INFANT FEEDING. J. V. C. Braithwaite. 140 pages. New York: Wm. Wood & Co., 1930.

This little volume purports to be a simplified brief discussion of infant feeding, intended for general practitioners. Its early chapters on breast feeding and the physiology of digestion are very well done; thereafter, for the American physician, at least, it leaves much to be desired. It is my impression that infant feeding, as taught in the United States, is well in advance of what this British writer portrays. Fame still awaits the pediatrician who can, readably and simply, discuss this subject in brief manner.

THOMAS MYERS, M.D.

A PRACTICAL MEDICAL DICTIONARY. Thomas Lathrop Stedman. Eleventh edition, revised. Price $7.50. New York: Wm. Wood & Company, 1930.

The eleventh edition is referred to by Stedman as "a thoroughly revised edition." In the preface, reference is made to the successful struggle to attain purification of medical orthography after two decades of patient effort. The primary function of a medical dictionary is listing definitions brief and accurate. In the reviewer's opinion, the author has attained his goal.

The source of the words are noted. Simplified spelling of medical terms is given; the older spellings are given as alternatives.

The plates of (a) autonomic nervous system, (b) surface areas related to spinal cord segments, (c) protozoan parasites, and (d) changes in the morphology of the blood are beautifully colored. Other plates, picturing, for instance, blood vessel system, nervous system, muscular systems, leave something to be desired. One wonders why this should be so. Upon reading the index of plates, the page for lymphatics is given as 1105; one must, however, turn to page 1130 to find this plate. There is no plate referring to the structures of the ear.

Beyond these few criticisms, however, one is impressed with the usefulness and the fund of material contained in this newly revised dictionary.

J. C. MICHAEL, M.D.

THE MEASUREMENT OF MAN. J. A. Harris, C. M. Jackson, D. D. Paterson, and R. E. Seammon. 215 pages, with 87 illus. Price: $2.50. Minneapolis, Univ. of Minn. pr., 1930.

This book, as the title implies, is of an academic character. The contents, first presented as lectures before the Sigma Xi society of Minnesota, are four monographs, each apportioned to some phase of human measurement. The co-authors in their respective chapters are recognized immediately as eminent scholars and teachers, all of whom at the time of writing were faculty members at the University of Minnesota.

The first chapter, The Measurement of Man in the Mass, by Dr. J. A. Harris, now deceased, and formerly head of the Department of Botany, is a concise presentation of the elements of biometrics, the application being made to the human. Formulæ are developed and appropriate explanations and illustrations are given. This chapter can be recommended for study as a valuable guide in the presentation and interpretation of the human data in the mass, which would necessarily include medical statistics.

The second chapter, Normal and Abnormal Human Types, by Dr. C. M. Jackson, head of the Department of Anatomy, is a presentation of material showing anatomical differences between races in Europe. These comparisons are then carried on into their descendants in the United States by means of data obtained from army records and student measurements at various colleges and universities, including the University of Minnesota, lending an element of fact to the sport reporters' adage, "Giants of the North." Types of bodily build are then discussed, including variations attributable to ductless gland dysfunction. The chapter closes with an interesting table relating bodily habitus to a diversity of diseases.

The third chapter, Personality and Physique, by Dr. D. G. Paterson, Professor of Psychology, begins with an observation of the general beliefs in the relationship of physical characteristics to mentality. A careful repudiation is then made of the pseudosciences of physiognomy and phrenology. This includes the records of a number of investigations undertaken in an effort to approve or disprove various assertions of the physiognomists and phrenologists.

The author then enumerates and discusses a number of investigations involving mental capacity and various physical characteristics including physical health, one of the most interesting of which compares a group of children in whom tonsillectomy and adenoidectomy have been done to a group of similar children not operated upon. No correlation was found between increased mentality and tonsillectomized children. The last named group, the children without operation, on the contrary proved to have advanced faster in mental age with interval Binet tests than the group in which operation was done. The summary embodies an apology for the negative evidence which the author has presented in the article.

The fourth chapter, the Measurement of the Body in Childhood, by Dr. R. E. Scammon, until recently Professor of Anatomy, now dean of the Department of Biology, University of Chicago, enters immediately into a presentation and discussion of growth data. Four types of postnatal growth are developed, namely—the general, the neural, the lymphoid and the genital types. The postnatal growth of certain of the ductless glands is discussed separately as it does not fit into any of the previously mentioned types. A brief discussion of the comparison of prenatal and postnatal growth is then presented. The final chapter is devoted to a discussion of what the author chooses to name "velocity of growth."

The book as a whole is very readable. While it is not a textbook in any sense, much information is presented which is of value. The book would be an addition to any library and transmits the desire to be reread at intervals.

Claude J. Ehrenberg, M.D.

PRACTICAL TREATISE ON DISEASES OF THE DIGESTIVE SYSTEM. L. Winfield Kohn, M.D., F.A.C.P. 2 vol. Price, $12.00. Philadelphia: F. A. Davis Co., 1930.

This two-volume work of 1,073 pages exclusive of the index is small enough to be very inviting and convenient, yet detailed and complete enough to be very worth while, both for general reading and as a reference book. It is profusely illustrated with 550 illustrations. Most of these are simple, well chosen, and well executed drawings. There are also a number of photographs of patients, pathologic specimens, reproductions of roentgen films and gastro-photo views, and several very fine color reproductions of gastroscopic views.

The sections on anatomy and physiology are very interestingly written without entering too deeply into involved or controversial questions. In a later chapter the neurology is most splendidly described and what is probably the most outstanding feature of the work is the Chapter on Clinico-physiological Considerations, in which the relationship between symptoms and disturbed physiology is beautifully emphasized.

The Chapter on Physical Examination brings out anew the importance of developing experience, skill and keenness of observation rather than leaving too much to accessory methods. Special emphasis is given to percussion in eliciting tenderness and to ausculation of the abdomen.

An especially interesting chapter is that in which esophagoscopy, gastroscopy and intragastric photography are discussed. Their possibilities and limitations are nicely weighed and the illustrations of technic and findings are illuminating.

Laboratory methods and interpretations of findings are given in detail.

The chapter on Fluoroscopy and Radiography is noteworthy in that it describes so well, and illustrates so impressively with silhouette drawings, the normal variations in size, shape and physiology, as well as typical variations in disease, and the technics which are helpful in disclosing the variations.

Following all these preparatory chapters the diseases of the digestive tract are taken up in order in typical textbook fashion, giving their symptoms, physical findings, laboratory and roentgen evidences, differential diagnosis, pathology, prognosis and treatment, all very interestingly and readably written. Here, in contrast to the silhouette drawings of a previous chapter, are found abundant illustrations of disease, in reproductions of X-ray films of actual cases, showing the applications of the principles taught by the more pedagogic drawings.

A section of the second volume which alone makes the whole work very much worth while is that which is devoted to diseases outside of the digestive system which cause abdominal or gastro-intestinal symptoms. This furnishes a splendid correlation and guards against too circumscribed gastro-intestinal thought.

Dr. Kohn is no therapeutic nihilist. After giving us a most splendid, though not too long, treatise on the gastro-intestinal tract, its diseases and their diagnosis, together with treatment of each one as encountered, he goes on to produce for us a wealth of therapeutic suggestions. Seventy pages are devoted to diet. The requirements for the various diseases, the properties of the various foodstuffs and their proper preparation for pathologic conditions are well described, together with many helpful diet lists for various diseases. Mechanical and all other physical therapy is generously described and evaluated, even the much questioned colonic irrigation and its technic with the arguments pro and con are well presented for our consideration. When it comes to medication an especially rich storehouse of material is laid before us. Page after page of good prescriptions are given, with the symptoms and pathology for which they are helpful. One can find here a considerable stimulus to his resourcefulness, a jog against falling into a narrow routine, against a sense of mild hopelessness if things go not too well, and against amiably prescribing the last detail man's plausible suggestion at ten or fifteen cents per capsule.

A short chapter by Zachary Cope gives the indications for and the results which may be expected of surgery. Only a suggestion of technic is given. Half of the chapter is devoted to acute surgical conditions.

Not the least of the fine features of the work is the very complete and satisfactory index which makes for quick reference to interesting symptoms, pathology or procedures.

On the whole the book is concise, very well written, and sufficiently inclusive to be a great practical help in practice.

Ralph T. Knight, M.D.

CANCER: ITS ORIGIN, ITS DEVELOPMENT AND ITS SELF-PERPETUATION. Willy Meyer, M.D., Consulting surgeon to the Lenox Hill and Postgraduate Hospitals, etc.: Emeritus Professor of Surgery, N. Y. Postgraduate Medical School. Cloth. Price, $7.50. Pp. 427. New York: Paul B. Hoeber, Inc., 1931.

The author "never intended to write" this book. His purpose was to prepare three articles on cancer. In so doing he perused a prodigious literature, and, like Adami, became "pregnant with book." He emerged from "the literature," which, like the Sargasso Sea, holds something of everything within depths, with "disconnected observations, bunched like the stars in the nebulæ of the heavens with gaping voids between the nebulæ." In order to give coherence and sequence to his material, he resorts to speculation as his only tool, and he offers the book as "an experiment, an experiment in path-finding."

To have cancer there must be a systemic predisposition. This may be hereditary on the basis of an insufficiency of the vegetative nervous system; or a similar state may be reached by strain. Once reached, this condition leads to a systemic predisposition through a predominance of potassium in the serum salts producing a chronic systemic irritation, accentuated by age. This is the constitutional factor. To produce actual cancer the second factor of local irritation must be introduced. In this manner dead tissue is left unabsorbed and acts as the local irritant; misplaced embryonic cell rests, etc., may act similarly. The combination of these two factors makes the precancerous state. There ensues a sequence of chronic cell death, necrone (cell protein decomposition products) formation, stasis, impaired cell permeability, cell proliferation and crowding. The process, as yet reversible, may continue on to definite cancer, and become irreversible. The same set of factors continue to work, so that by now the tumor is both cause and effect. The difference between carcinoma and sarcoma lies in the concentration of the necrone solution; at its highest, the epithelial tissue is dissolved, leaving nothing but a highly malignant connective tissue.

From the standpoint of therapy, he recognizes four phases: (1) the chronic systemic irritation, (2) the chronic local irritation, (3) the presence and joint activity of both factors, producing the localized operable cancer, and (4) the progress of the process to the point of generalized malignancy and metastasis, or inoperable cancer. Phase 1 becomes an obvious field for research; phase 2 is the basis of our present anti-cancer propaganda; phase 3 is the realm of surgeons and radiologists; phase 4 must be approached by changing the serum reaction from alkaline to acid—the production of a state of acidosis—and the removal of as much of the necrone-producing cancer substance as is feasible. If a successful therapeutic attack alone could be made upon a phase 4 cancer a lethal dose of necrones would be released from the decomposition of unremoved cancer tissue. The intervention of surgery is thus assured in any circumstance.

E. C. Hartley, M.D.

WANTED—Physician to share offices with dentist and physician in Lowry or New Lowry Building. If interested call Cedar 8618.

FOR SALE—Small rural hospital. All modern. Worth $25,000. Will sacrifice for $16,000. Instruments and equipment included. $5,000 cash. Balance time at 6 per cent. Address D-130, care Minnesota Medicine.

FOR SALE—Medical practice and complete office equipment in southern Minnesota town of 2,700 people of mixed nationalities. Collections excellent. Practice established 24 years. Reason for selling—death. Address D-131 case Minnesota Medicine.

WANTED—Salaried appointments for Class A Physicians in all branches of the medical profession. Let us put you in touch with the best man for your opening. Our nation-wide connections enable us to give superior service. Aznoe's National Physicians' Exchange, 30 North Michigan Ave., Chicago. Established 1896. Member The Chicago Association of Commerce.

BE PREPARED to give your patient a complete examination. Why send patients away? Office space for rent in central district including two rooms and X-ray and clinical laboratory in connection. $50.00. Address D-134, care Minnesota Medicine.

FOR RENT—Desirable space on sixteenth floor Medical Arts Building, Minneapolis. Call Geneva 7685.

POSITION WANTED—As assistant in doctor's office. Graduate laboratory and X-ray technician, Swedish Hospital, Minneapolis. Business experience. Address D-133, care Minnesota Medicine.

INSTRUMENTS FOR SALE

An exceptionally complete set of surgical instruments and office equipment, property of the late Dr. Lyng, is for sale. Especially suitable for hospital. May be seen at 5145 Woodlawn Avenue, Minneapolis. Telephone Dupont 8948.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

EXAMINATION REPORT DECEMBER 2, 1930.

A CONSIDERATION OF SECONDARY ANEMIA*

W. H. Long, M.D.
Dakota Clinic
Fargo, North Dakota

THE frequency with which we encounter patients with secondary anemia justifies a review of the subject. Their successful management depends upon the ferreting-out of the primary cause of the condition and remedying that condition. We must carry out active measures directed to the restoration of the blood to normal. A prescription for Blaud's mass and the advice, "Eat plenty of liver," will not suffice.

The term secondary anemia includes two groups: the anemias which can be attributed to a primary cause, and the group of cases which present similar characteristics but which must be classed idiopathic secondary anemia because we are unable to ascertain the primary cause. The primary cause may be increased blood loss from hemorrhage, either acute or chronic, or deficient blood formation from depression of the marrow by the presence of toxins of various origin.

The blood findings characteristic of secondary anemias are definite. The hemoglobin reduction is prominent, and the red count less strikingly reduced. This gives us constantly a color index of less than one. The leukocytes are normal in number except in long-standing cases where the bone marrow has become exhausted. The stained smears show achromia or faint staining and a tendency of cells to be smaller than normal with varying degrees of deformity. With an active marrow there is a considerable polychromatophilia, while in long-standing cases, with a depressed marrow, very little is to be found. Reticulated cells are found in about the normal percentage.

The classification of secondary anemias, according to the grouping suggested by Watkins, is interesting and will prove helpful in further study of these cases. We have followed the shift in the leukocyte counts in these cases under treatment and, in prognosis, the careful study of the leukocytes is helpful. The cases with pronounced shift to the right are certainly more resistant to treatment.

Certain cases are encountered with a color index near one and perhaps with an associated achylia which are difficult to distinguish from primary pernicious anemia. The determination of the volume index, which is a measurement of average red cell volume, is helpful. The demonstration of increased bilirubin by the Vandenberg reaction or the icterus index test, which indicate increased blood destruction, may decide the proper classification. We have used the therapeutic test of feeding ordinary liver extract and following the reticulated cell count in two border-line cases, the absence of reticulate response being against the primary pernicious type.

The cases most easily recognized are those due to acute hemorrhage. The history usually is significant. Certain fundamentals are, at times, forgotten in managing such cases, and these may cause serious error. For instance, the hemoglobin and red blood count are not likely to be altered until six to twelve hours after the acute hemorrhage. The leukocyte rise is prompt and may reach 15,000 to 18,000. The predominant leukocyte is the polymorphonuclear. These points should be remembered in deciding between the possibility of intestinal tract hemorrhage and infection and in appraising the severity of hemorrhage. Following the leukocyte and platelet counts in intra-abdominal hemorrhage can be very helpful in the management of such cases. In all cases of acute hemorrhage, the determination of the presence of a blood dyscrasia, as the primary or as a complicating factor, is important. In purpura, the leukocyte count is likely to be lower and the platelet count is constantly low, the bleeding time increased and the clot does not retract normally.

---

*Read at the meeting of the Northern Minnesota Medical Association, Moorhead, Minnesota, September 20, 1930.

The two following cases are typical examples of those due to blood loss and are cited to illustrate how little the patients were impressed by that blood loss and how closely they must be questioned to bring it out.

Miss D. P., aged 16, was referred as a case of chlorosis. The week before she had felt light-headed, dizzy and had had some headache. She became very tired, short of breath on climbing stairs, and three days before she had fainted. On direct questioning, after some hesitation, she remembered that the stools had been dark the past three days and that, for the past month, she had had an uncomfortable hungry sensation in the epigastrium in the mid-morning and mid-afternoon. The hemoglobin was 24 per cent, red blood count 1,220,000, white blood count 6,500, platelets 176,000, bleeding time 3 minutes, coagulation time 4 minutes, and the stool contained blood (Grade IV) and the X-ray revealed a duodenal ulcer.

R. B. P., aged 17, presented almost an identical history, attributing all his symptoms to the extreme heat of the summer and having overlooked entirely his black stools and having thought nothing of his hunger pains, both symptoms having been elicited only by the closest questioning.

Chronic blood loss is a much more frequent cause of secondary anemia. Here there are a long list of conditions which must always be considered: peptic ulcer, hemorrhoids, diverticulitis, intestinal polyposis, cirrhosis, menorrhagia—and it is surprising how frequently the patient has not been at all concerned by considerable amounts of continued blood loss. Here, again, it is essential to exclude possible complicating chronic purpura and, also, to determine the activity of the marrow by study of the presence of nucleated cells, polychromatophilia and the leukocytic type.

The two following patients presented themselves for the treatment of their anemia.

Mrs. G. L., aged 32, the mother of two children, gave a history of irregular menstruation lasting seven to fourteen days and requiring nine to ten pads daily. She had noticed that she bruised easily. Her father was subject to severe nose bleeds. Her mother bled excessively and a sister bleeds easily and excessively. The laboratory reported: Hemoglobin 25 per cent, red blood count 2,670,000, white blood count 8,850 (p. m. n. 75.5 per cent, lymph. 21, mononuclear 2, transitional 4.5), anisocytosis II, poikilocytosis II, achromia II, bleeding time 3 minutes 35 seconds, coagulation time 8 minutes 30 seconds, platelets 84,000, normal retraction of clot.

The uterus was found to be slightly enlarged and of the hard fibrous type and a small mass was present in the right adnexa.

Dietary treatment with iron, arsenic and calcium was instituted.

One month later the hemoglobin was 39 per cent, red blood count 3,780,000, white blood count 6,500, platelets 112,000.

Following three transfusions the hemoglobin was 50 per cent, red blood count 4,730,000, white blood count 7,900, platelets 264,000.

On August 6, 1930, a fibroid uterus and cystic right ovary were removed. The spleen was examined and found not enlarged.

The transfusions brought about marked general improvement but the blood count did not improve satisfactorily. But for the right pelvic mass, radium or X-ray might have been used to induce temporary cessation of the menses until the blood had been restored to normal. The question of the presence of a chronic, hemorrhagic purpura was difficult to settle with the low platelet counts, but I think this diagnosis was not justified because of a normal bleeding time and a normal retraction of the clot.

Another such case was that of Mrs. P. E., aged 20, who had suffered from menorrhagia two years before but not since her marriage at the age of nineteen.

Her hemoglobin was 55 per cent; r. b. c. 4,900,000; w. b. c. 5,400. A mass was found in the right adnexa which proved at operation to be a cyst of the ovary. This and a small cyst on the left tube were removed.

In 1926 the patient was seen again. At this time, the blood showed a hemoglobin of 35 per cent; r. b. c. 4,170,000, index .4 plus; w. b. c. 7,150. The menstrual flow had been excessive and irregular, and a mass was present in the right adnexa.

At operation August 9, 1926 a double salpingectomy was performed for bilateral salpingitis and a right tubo-ovarian abscess was removed. Two transfusions were given. The hemoglobin rose to 42 per cent.

In spite of operation, the excessive flow continued and, on March 1, 1927, radium was given to produce complete cessation. General improvement was prompt and has continued well since. Hemoglobin has continued rather low, never exceeding 50 per cent until the past year. The blood picture now shows a hemoglobin of 76 per cent and r. b. c. 4,800,000. There were never any manifestations of purpura.

Certainly these cases are trying and it seems as though certain individuals are endowed with a poor hemopoietic system. They show poor response to stimulating measures and are very susceptible to any chronic loss of blood.

The third and very common type of secondary anemia is that associated with chronic toxemias and infections. Common causes are tuberculosis, syphilis, chronic focal infections, malignancies, nephritis, and pregnancy. Faulty diet, poor hygiene and actual dietary deficiencies often play a large part in these. There is defective blood formation and likely some measure of increased blood destruction.

The blood picture in such cases is not characteristic. If long continued, the state of semi-aplasia may become established. The smears should be studied for evidence of exhaustion of the marrow.

Of special importance are the anemias of pregnancy. We have encountered an unusually large number of patients with rather high degrees of anemia in the last trimester of pregnancy. In some of these, recovery has been very slow and, even after delivery, they have remained under par for long periods. It is important to ascertain its presence early, as the earlier treatment is carried out the better the result. Recently there have been numerous reports in the literature on the anemias of pregnancy and I think the condition is best summarized by Pepper as follows:

1. A mild anemia occurs physiologically in pregnancy.
2. The physiologic anemia may become severe in individuals previously anemic, also as a result of hemorrhage or of complicating infections, of which syphilis is apparently the most important.
3. Severe so-called pernicious anemia of pregnancy is not identical with Addisonian anemia (primary pernicious anemia). The grade of anemia may be as marked and certain features of the blood picture suggestive, but other essential criteria are lacking.
4. Sepsis may be the cause of such an anemia and the lack of leukocytosis does not exclude this possibility.
5. Early recognition of anemia beyond the "physiologic" grade, and prompt treatment will, in the majority of instances, avoid the development of the more severe grades of anemia, which, in the past, have been termed "the pernicious anemias of pregnancy."

The anemias associated with nephritis have likewise been the subject of many reports recently. The condition is so constant and the degree of anemia so parallels the severity of renal damage that it can be used as a reliable prognostic guide. The most complete report is that of Ashe, who studied 300 cases and concluded that the degree of anemia could be very helpful in deciding the degree of renal damage in cardiovascular-renal disease.

The anemias of syphilis, of chronic infections, arthritis, and of chronic ulcerative colitis are likely to be severe and are peculiarly likely to have an associated splenomegaly.

Possibly splenic anemia should not be mentioned, but, inasmuch as the anemia is of a distinctly secondary type, it is included. The essential features in such cases are the marked leukopenia and the associated hepatic cirrhosis.

One patient observed presented herself in October, 1926, because "she was run down." Her hemoglobin was 45 per cent, r. b. c. 3,240,000, index .7, w. b. c. 5,700. Examination was negative except for a severe sinus infection. The sinuses were operated upon and she was placed upon a suitable diet, iron and arsenic. Two months later, the hemoglobin was 60 per cent, r. b. c. 4,120,000, and the general condition much improved. At that time, there was a question as to whether or not the spleen could be felt. She returned in October, 1928, stating she had been well for one year after the last visit, when she began to have epigastric distress of an indefinite type and became weak and run down again. The blood picture was: Hemoglobin 35 per cent, r. b. c. 3,030,000, index .5; w. b. c. 1,750, platelets 162,000, p. m. n. 5, lymph. 78, trans. 10, mono. 5, anisocytosis II, poikilocytosis II, polychromatophilia slight. The spleen was markedly enlarged and hard. Splenectomy was performed November 24, 1928. Recovery was prompt, the blood picture improved rapidly, and one month later the hemoglobin was 64 per cent, r. b. c. 3,950,000, w. b. c. 5,200 on leaving hospital. She was heard from during the past summer and has remained in good health.

Why some individuals develop these rather severe degrees of anemia with these infectious processes and others do not is an interesting speculation. That they have a definitely vulnerable hemopoietc system is suggested by the occasional definite familial involvement. The following two families are mentioned because of the several members observed:

Mrs. C. W. C. was found upon examination to be suffering from amebiasis and a pelvic tumor, the nature of which was not determined. She had not suffered from menorrhagia. There was no free hydrochloric acid in the stomach contents. Her blood picture showed a hemoglobin of 35 per cent; r. b. c. 4,030,000; w. b. c. 6,900. She had been treated for anemia for the past four months.

Mrs. R. S., a sister, was found to have dental sepsis.

An endocervicitis and a blood picture showed the hemoglobin 55 per cent; r. b. c. 3,760,000; w. b. c. 5,950. She also had no free hydrochloric acid in the stomach.

Mrs. C. W. C., another sister, was found to be suffering from chronic constipation, chronic sinusitis, and had a hemoglobin of 40 per cent; r. b. c. 3,600,000; w. b. c. 6,250. She too had no free acid in the stomach contents.

These patients have all been restored to health, the first by eradicating the amebic infection and two transfusions. The other two did not require transfusions. A fourth sister was seen with a gastric cancer.

In the other family, Mr. E. G. presented a typical picture of primary pernicious anemia (hemoglobin 52 per cent, r. b. c. 1,880,000, index 1.4, w. b. c. 4,950). There was no free hydrochoric acid in the stomach contents and there was a history of glossitis. Stool examination showed many *Balantidium coli* present. It is interesting to note that the parasite was promptly eradicated by a series of neoarsphenamin treatments but the course of the disease not affected. He was seen first in 1927, is still under observation and promptly relapses if he neglects taking liver extract.

A sister, Mrs. A. F. N., aged 29, was found to be suffering from a sinusitis and dental sepsis. Her hemoglobin was 30 per cent, r. b. c. 3,490,000, index .4, w. b. c. 5,800. There was no free hydrochloric acid in the stomach contents. Neurological findings were normal.

Another sister, Mrs. C. S. G., aged 32, suffered from menorrhagia caused by a fibroid uterus. Her hemoglobin was 48 per cent, r. b. c. 3,760,000, index .6 per cent.

The treatment of secondary anemias consists in:

1. The care of the primary cause when it can be found.
2. Supplying adequate iron.
3. Stimulation of the hematopoietic organs.

Chronic blood loss from menorrhagia is certainly one of the most frequent causes encountered. In young women and girls, striking reduction in flow has frequently been obtained by one or two stimulating doses of X-ray to the ovaries. In more severe cases, we have induced temporary cessation by heavier doses of X-ray or by radium. In patients approaching the menopause, we give sufficient radiation to obtain complete cessation.

A supply of adequate iron is insured by feeding foods high in iron content and the administration of ferrous carbonate or of reduced iron. Whipple found certain fruits (apricots, prunes, and raisins) had a decidedly better effect than vegetables in restoring the blood after repeated blood losses. Of vegetables, spinach was the only one that was of special benefit. Our practice is to give a well-balanced diet, high in vitamins, with plenty of red meats, green vegetables, whole wheat bread, fruits and a daily portion of liver or kidney.

The use of liver in secondary anemia has been reviewed innumerable times in the literature since its use has become fixed in the primary anemias. Strikingly convincing are the reports of Whipple and of Keefer and Yang. Whipple found that dogs, rendered anemic by blood loss, regenerated their blood much more rapidly when fed on diets rich in liver and kidney rather than when fed muscle meat. Keefer and Yang followed the daily fluctuation in hemoglobin, red counts and the reticulated cell response in thirty-seven cases of secondary anemia and concluded that liver and iron, given in combination, were more effective than either given alone. In a more recent communication, Whipple reports the isolation of a palatable liver fraction potent in anemia due to hemorrhage. Such an active extract for use in secondary anemia will be a distinct addition to our present methods. Giffin has recently reported on the use of fetal liver, but that is very hard to obtain and is not likely to become readily available.

One method of stimulation of blood formation which is too often neglected and which practically never fails us is the use of transfusions. Two or three transfusions will restore these people more rapidly than any other means. The citrate method is entirely satisfactory, the reactions are but few and seldom severe. In any patient who is at all slow to respond and especially if there are any signs of semi-aplasia (that is, low white blood count, low polymorphonuclear count, low platelet count and absence of polychromatoplasia), we transfuse at once.

Arsenic is very valuable as an adjunct. Many times where ferrous carbonate alone has failed, addition of arsenic has brought about prompt improvement. We have used bone marrow extract in the form of hemogennin without especially significant results. Ultra-violet radiation, natural or artificial, is an important aid. The use of copper with iron has given us some strikingly good results.

SUMMARY

1. Secondary anemia must be treated first by removal of the primary cause.
2. Care must be taken to exclude chronic pur-

pura in all cases of acute or chronic blood loss.

3. Closest consideration of the history is required in determining blood loss as the patient is often not sufficiently impressed.

4. Adequate dietary management to include abundance of vitamins, iron-containing food and the long-continued use of liver and kidney, as well as muscle meats, is important.

5. Drugs in the form of iron and arsenic have not been supplanted by newer means.

6. Transfusions are practically never-failing and are too often omitted in the management of secondary anemia.

AVERTIN

The Council on Pharmacy and Chemistry reports that Avertin was submitted for consideration in February of this year; that it recognizes the fact that the product presents certain desirable properties but that definite action concerning its recognition is postponed pending investigation of certain of its side actions now being conducted. For the information of the medical profession the Council submits a report concerning the present status of the drug. Avertin is tribrom-ethanol. It was introduced in Germany in 1926, to be used alone for rectal anesthesia, or to be supplemented by other narcotics, including morphine and ether. Later Avertin was offered in a solution, 1 c.c. of which contains 1 Gm. of Avertin dissolved in amylene hydrate (tertiary amyl alcohol). This solution has been the subject of several hundred reports. After reviewing the reported advantages and disadvantages the Council concludes: though the present evidence indicates that Avertin may prove valuable as a means of initiating narcosis but not for complete narcosis, the Council decided not to admit the drug to New and Non-official Remedies. (Jour. A. M. A., November 8, 1930, p. 1427.)

DISINFECTANTS

In combating contagion, modern sanitary practices have eliminated disinfectants for spraying walls, ceilings and floors of school rooms. The source of infection is the individual; so long as the infected individual is present in the room, any disinfectant that might be used on the walls or the floor would be of little if any value in preventing infection. Removal of the infected individual usually suffices to end the danger of spreading the infection. Soap and water is the best agent for cleaning floors, together with plenty of fresh air and sunshine. Terminal disinfection, such as fumigation with formaldehyde, has been generally discarded as valueless. In the case of lavatories, urinals and toilet bowls, so-called germicides in reality accomplish nothing except covering up the primary odor by the stronger odor of the chemical used. "Disinfection of hands" may be obtained by a thorough scrubbing with soap and water. In laboratories in which pathologic material is being handled, a solution of mercuric chloride or a solution containing "compound solution of cresol" may be employed. (Jour. A. M. A., March 28, 1931, p. 1098.)

ENDOMETRIOSIS*

FRANK E. KLIMAN, PH.C., B.A., M.D.
Duluth, Minnesota

MANY theories have been advanced to account for the presence of endometrium-like tissue in such places as the ovary, recto-vaginal septum, uterus, and in extragenital locations. No one theory, however, has been adequate to explain the origin of all these heterotopic growths.

The existence of endometriomata was known as early as 1899, when Russel reported the first case of endometriosis of the ovary. Due to the fact that cells of the germinal layer dip into the ovarian stroma and are cut off from the parent structure, they cannot be distinguished from endometrial glands. Because of his knowledge of this phenomenon, Russel claimed that endometriomata originated from the germinal epithelium.

Cullen holds that endometrial growths arise from aberrant Müllerian rests. Sampson, on the other hand, supports the view that endometrial cysts are the result of implantation and development of uterine epithelium which has escaped, with menstrual blood, through the Fallopian tubes. Other authorities disagree with Sampson, claiming that if his view were correct we should expect to find more cases of endometriosis following such uterine manipulations as curettage, transuterine insufflation, lipiodol injections, etc. Halbane believes that endometriosis spreads along the lymphatic channels, whereas Lockyer has brought out the serosal theory.

The serosal theory is based on investigation which shows that all genital epithelia are derived from the urogenital fold. From this fold are developed the lining of the Müllerian ducts, the germinal epithelium of the ovary and the pelvic peritoneum. Hence, the endometrium and lining of the tubes are considered as modifications of the pelvic peritoneum. Lockyer accordingly believes that, since the pelvic peritoneum and germinal epithelium originate from the same layer, any abnormal hormonal stimulation may initiate a regional differentiation into endometrium. In reviewing the theories that have been advanced, the "serosal theory" comes closest to being correct. It seems to account for all forms of endometriosis, whether in the ovary, pelvic peritoneum, inguinal canal or recto-vaginal septum.

Endometrial growths are governed by the ovaries just as is the normal endometrium. This view is strengthened when we note their histological structure, reaction during pregnancy, and the characteristic cyclic changes occurring in them during menstruation. That there is a continued activity in ectopic endometrium in the presence of functioning ovaries, is a well known fact. It is also known that misplaced endometrial tissues cease to function when ovarian hormonal activity is removed by ablation of the ovaries surgically or otherwise.

It is not my purpose in this short paper to cover the whole field of endometriosis, but to confine myself to endometrioma of the recto-vaginal septum, report a case, and sketch the treatment used in this condition.

From the standpoint of treatment, endometriomata or adenomyomata of the recto-vaginal septum are divided into four main groups.

Isolated, discrete nodules in and freely movable with the vaginal wall are placed in Group I. This type is quite rare.

Group II includes those small tumors in the upper part of the vaginal wall, as a rule posterior to the cervix and occasionally attached to it, but not involving the rectum. In this same group are those tumors found posterolateral to the cervix, extending into the uterosacral or into the base of the broad ligament. Those tumors when about 1 cm. in diameter are usually smooth and globular. When they grow larger they become irregular, due to the formation of new nodules.

Group III takes in those tumors involving the supra-vaginal portion of the cervix, upper portion of the vaginal wall and anterior rectal wall, but which are still confined to the pouch of Douglas. The ureters, lateral walls of the rectum, and uterine adnexæ are not involved. A puckered vaginal or rectal wall, bluish or slate colored, marks the site overlying the tumor nodules. The puckering is due to attachment of the vaginal or rectal walls to the nodule. The picture is that of a blue dome cyst in the breast.

Group IV.—To this group belong those tumors originating in the recto-vaginal septum, but which spread so as to involve cervix, vagina, rectum, broad ligaments, and may surround and constrict the ureters and mat the pelvic structures into an almost homogeneous mass.

---

*Presented before the St. Louis County Medical Society, Duluth, Minn., November 13, 1930.

The symptoms and signs vary according to the size of the growths and the viscera involved. Groups I and II rarely produce symptoms and are discovered on routine examination. Tumors in Group III, on the other hand, produce lower abdominal pain, dull or grinding in character, tenesmus, pressure and fullness in the rectum, aggravated by defecation and during the premenstrual period. Occasionally there is bleeding from the rectum, which leads to a diagnosis of hemorrhoids. In the intermenstrual period, since the tumor does not swell, the above symptoms are diminished or absent. Menorrhagia or a prolonged duration of the period is usually present.

In group IV, in addition to the above mentioned symptoms, there is pain and tenderness of the tubes and ovaries. Further, we find the symptoms of hydro-ureter, unilateral or bilateral, as well as pyelitis, where secondary infection has occurred as a result of stasis caused by the constricting growth. These symptoms, as mentioned before, are increased just before and during menstruation, as a result of the ovarian activity on the endometrial tissue.

Treatment is dependent upon the size and location of the tumors as well as the structure involved. Tumors in Group I and those in Group II which are attached to the cervix but do not involve the uterine ligaments are treated by surgical removal through a vaginal incision. Where the dissection is difficult it is better to use radium in order to avoid the formation of a recto-vaginal fistula. For tumors in Group II, involving the uterine ligaments, Cullen advocated extensive dissection. He reported cases in Group III as well, where he resorted to surgery, occasionally resecting rectum, sigmoid and bladder. In a later series of cases Cullen observed a decrease in the size of the tumors involving rectum and bladder where no resection, but only ablation of the ovaries was the treatment. This evidence indicated that absence of the ovarian hormonal activity caused the same atrophic changes in the tumors as it did in normal endometrium.

It is now advised by many authorities that tumors of all groups are best treated by means of radium, X-ray, or a combination of both.

The following case is reported in which radium and X-ray were used successfully:

Mrs. E. W., aged 31, married, consulted me on March 1, 1930, for a shooting pain in her right side present for a week. There was no nausea or vomiting but the patient suspected a return of a pylorospasm (for which she had been treated eight years previous) or an attack of appendicitis.

On questioning, the following history was elicited. The menses started at thirteen, occurred regularly at twenty-eight day intervals but since her marriage were seven days in duration. As long as she could remember she had had pain in her rectum three to four days before each menses. This pain was worse when she was nervous. She was examined on several occasions and advised that she had hemorrhoids. There was no loss of weight, but the patient fatigued easily. While she was not nervous, she was more irritable than usual. The cardiovascular and pulmonary history was negative. She also had had several examinations to determine the cause of her sterility. These examinations were quite complete except that she had not had a Rubin test (likely examined before the test was used).

Past illnesses.—The patient had had a curettage and rectal dilatation and had been treated for albumin and casts in the urine, for low blood pressure, and for a pylorospasm.

Family history.—Aside from the fact that her mother has Bright's disease, the family history was negative.

Physical examination.—The patient was of slight build but well nourished. The head and neck were normal except for slight thyroid enlargement. Heart and lungs were normal. The pulse was 84, temperature 98.2, blood pressure 110/70. There was slight tenderness over McBurney's point but none in the epigastrium. A slight tremor was present in the fingers.

Pelvic examination.—The vulva was normal. The introitus admitted two fingers. There was no vaginal discharge, erosion of the cervix, nor laceration present. The uterus was small and freely movable, normal in size, position and shape. The left ovary and adnexa were normal. The right ovary was prolapsed and tender. Just posterior to the cervix a hard, non-sensitive nodular mass the size of a marble was felt in the midline. The mass was bluish in color and appeared to be in the recto-vaginal septum.

Laboratory examination.—Urine normal. White blood count 8,700. Red blood count 4,440,000. Hemoglobin 85 per cent. Basal metabolism rate plus 5. A diagnosis of endometrioma of the recto-vaginal septum, prolapsed ovary, and chronic appendicitis was made. The patient was advised to return for observation and a Rubin test.

On April 8, 1930, the patient returned still complaining of pain in the rectum, but now located more in the region of the anus. There were only occasional twinges of pain on the right side. Examination at this time revealed a tumor definitely palpable in the recto-vaginal septum the size of a walnut. There was a small blood cyst on the posterior lip of the cervix. The right ovary was the size of an egg, but not tender.

The right broad ligament was infiltrated and the mobility of the uterus was somewhat limited. Proctoscopic examination revealed a slate colored nodule the size of a hazel nut in the rectum, two inches from the anus, which bled easily when touched with a probe.

The patient was given 826 mgm.-hours of radium in two treatments at an interval of twenty-four hours. The radium was placed in the vagina against the growth and held in place with gauze. Filtration consisted of 2 mm. lead; 1 mm. brass; .5 mm. silver. In addition she received X-ray treatments over the abdomen and lower back.

Following radiation the patient suffered little ill effects save a diarrhea which lasted four days and a drawing sensation in the right inguinal region. Since radiation the patient menstruated twice. Proctoscopic examination revealed no further bleeding or ulceration and the growth had entirely disappeared, leaving only a depression at the original site. On vaginal examination the cervix was clean, there was no discharge or blood cyst present, the uterus was freely movable, normal in size, position and shape. The adnexæ were negative, although both ovaries were prolapsed and small. The growth behind the cervix was white in color and only the size of a pea. Abdominal tenderness was absent and the patient had had no more pains.

Because of several points of similarity to my case I present herewith the salient features of two cases reported by Heineberg.

Case 1.—A female, aged 27, had had regular and painless menses since their onset at the age of thirteen. She had had a curettage for uterine discharge. Later she developed pain in the hypogastrium radiating to the iliac region. There was distinct tenderness over McBurney's point. Both ovaries were tender and prolapsed and at operation were found bound down in the pouch of Douglas. The appendix was adherent to the right ovary and was removed. The patient was not relieved of her pain but in addition to the iliac pain suffered a sensation of fullness and pain in the rectum, especially before menstruation. Later examination revealed increase in the size of the left ovary, with thickning of the left utero-sacral ligament. At the second operation both ovaries were again adherent to the pouch of Douglas. The left ovary was the site of multiple cysts and three times the normal size. This was removed. Following operation the patient still had her pain in the rectum. The mass in the utero-sacral ligament became nodular. A diagnosis of adenomyoma was now made and the patient was treated with radium and had no further rectal pain.

Case 2.—The main symptoms in this case were pain in the rectum, accentuated before menstruation. Here, too, the appendix was removed because of iliac pain. Physical examination revealed a flattened nodular mass adherent to the posterior vaginal wall, cervix and rectum. The patient had the right tube and ovary removed without relief of her pain. Now, examination showed the tumor to be twice the size. The patient was treated by inserting four needles 12.5 mg. radium in the tumor for twenty-four hours. While she continued to menstruate the growth had decreased in size and her rectal pain disappeared.

SUMMARY AND CONCLUSIONS

1. The cases presented had many symptoms in common.
2. Rectal pain increased just before menstruation should lead the examiner to suspect endometrioma of the recto-vaginal septum.
3. Radium and X-ray, or a combination of both, is the treatment of choice because of less chance of formation of a recto-vaginal fistula, and the advantage of more complete ablation of ovarian activity.

OFFICE TREATMENT OF CHRONIC CERVICITIS*

SUSAN R. OFFUTT, M.D.
Rochester, Minnesota

THE chief objectives of treatment of chronic cervicitis are: (1) relief of annoying leukorrhea, (2) removal of a chronic inflammatory lesion which may be precancerous, and (3) elimination of a possible focus of infection.

In treating leukorrhea the etiology must be established. Gonoccocal infection of Skene's and Bartholin's glands may be the source of the discharge, and treatment should be directed against a specific type of infection. The discharge may be due entirely to vaginitis resulting from change in the chemical reaction of the secretion from the cervical glands that secrete mucus, or to the presence of the *Trichomonas vaginalis.* The most common cause of discharge is, of course, cervicitis, which may be primary, or associated with other inflammation.

Chronic cervicitis frequently is characterized by chronic erosion, and this may become later the site of epithelioma. Early carcinoma may be easily mistaken for simple erosion if the eroded area bleeds from contact with a swab on examination or if the velvety character of the surface is lost. Unless biopsy is obtained the diagnosis is not made until considerable valuable time has been lost to the patient.

The cervix must be considered as a possible focus of infection when all foci are being eliminated in the treatment of episcleritis, iritis and arthritis. Also, an infected cervix may be the source of pelvic cellulitis, of low grade, by extension of the infection from the cervix into the lymphatic structures, especially if there is extensive laceration of the cervix.

If the cervix of those women who have borne children is treated in the postpartum period, the entire problem of treatment of chronic cervicitis will be simplified. Whether immediate or later repair is made depends on circumstances. Neglect of postpartum cervicitis may mean later involvement of the upper pelvic structures, which may require major operation. However, most cases seen in the office are not in patients who are in the postpartum period but are of longer standing, due to previous trauma or infection.

Topical applications, such as mercurochrome, iodine, silver nitrate, and phenol, give temporary relief in many cases, but the deeper glands remain infected and the symptoms recur. Diathermy, injection of alcohol and medical ionization also clear up the disease superficially. All these methods give variable results from the patient's as well as from the physician's viewpoint. The infected cervical glands must be destroyed to get the best results, and this may be accomplished by cauterization of the cervix in the office or elsewhere by surgical treatment of the cervix.

If the lacerations are of marked degree, and if the cervix is edematous and angry-looking, it is well to put the patient to bed and to administer hot douches slowly; this results in shrinking of the cervix and may modify the extent of the operation necessary. If operation must be done, it is limited to simple trachelorrhaphy if possible; in more marked cases, a Schroeder or Sturmdorf operation is performed, and in the extreme cases amputation either by the knife or cautery is necessary. However, in the majority of cases the disease is milder, and can be treated in the office by the cautery, with or without anesthesia, depending on the extent of the lacerations and the infection present.

The technic of office cauterization is well established. Except for personal preferences concerning the type of cautery tip, the type of transformer, and the after-care of the patient, the technic is about uniform, and is well described and illustrated by Dickinson. The nasal cautery tip is placed against the area to be treated and the current is turned on. The diseased tissue is covered then by a number of incisions, depending on the depth into the tissue as well as the extent up the canal toward the internal os to which the process has penetrated. The important thing is completely to destroy the infected glands. Few patients complain of pain, and when they do complain of it it is not an unbearable pain; it is not pain in the cervix, but a dull aching across the lower part of the abdomen, similar to a menstrual cramp. This sometimes can be lessened by reducing the current. In most cases the necessary cauterization can be done at one sitting. If the patient is unusually nervous and complains of too much pain, or if the cervix can be only poorly exposed, anesthesia is then given. After cauterization the patient is advised to wear a pad and report every other day. I prefer not to use local applications to the cervix or to have the patient use douches, but to allow the sloughing to proceed without interference. The patient is examined every three or four days. The discharge, which at first is increased, usually stops in ten to fourteen days, but complete healing does not occur for about two months, depending on how deeply or extensively the cervix has been cauterized. After the sloughing is over, douches are used, and the cervix may be treated locally twice a week with mercurochrome, until healing is completed.

---

*From the Division of Medicine, The Mayo Clinic, Rochester, Minnesota. Read before the joint meeting of Chicago Medical Society and the Chicago Council of Medical Women, Chicago, Illinois, October 29, 1930.

There are three possible complications in cauterization of the cervix: (1) hemorrhage, (2) stenosis, and (3) pelvic infection. The bleeding seen after cauterization done in the office usually is slight and is due to oozing of the sloughing surface. Moderate bleeding at a given point can be stopped by lightly touching the bleeding point again with the cautery.

I have not seen any alarming hemorrhages from the cervix due to sloughing after cauterization done in the office, but I have seen profuse menstrual bleeding following the procedure when it was done near a menstrual period and precipitated menstruation. When this occurs, the patient is put to bed and is given ergot.

Stenosis rarely occurs after cauterization done in the office. Before the patient is dismissed from observation, the cervical canal is examined with a cotton applicator, and any filmy adhesions that may have formed are broken. Unless the cauterization has been too extensive and has included the internal os, complete stenosis will not occur. In case of stenosis, dilatation of the canal under anesthesia has to be done.

After cauterization of the cervix I have not seen any cases of pelvic infection nor any cases in which latent pelvic infection has been stimulated. Precautions are taken not to cauterize a cervix which is the seat of an acute infection, particularly one due to gonococci, with or without salpingitis. Cauterization is done midway between times of menstrual flow. Occasionally, it is necessary to cauterize the cervix a second time either because all the infected portions were not destroyed at the first cauterization or because reinfection has taken place.

SUMMARY

In treating leukorrhea, the etiology must be established. If it is due to chronic cervicitis, with or without erosion, superficial treatment will produce only temporary healing in many cases. The best results will be obtained by cauterization of the cervix in mild and moderately severe cases, or by operation in the extensive cases.

THE NEUROLOGICAL ASPECT OF HEAD INJURIES*

William H. Hengstler, M.D.
Saint Paul

THE subject of head injuries is one of vital importance today to every practicing physician and surgeon. With the vastly increasing accident rate, due to present day motor vehicle traffic, it behooves every medical man to be alert and well-informed in this particular field. Head injuries, in general, have always heretofore been considered as belonging to the realm of general surgery. Actually, however, a comparatively small percentage of them require any real surgical attention. Bruised and lacerated scalps, simple skull fractures without displacement of fragments, basal skull fractures and the like are, of course, fundamentally surgical, but these require so little actual treatment that they may be dismissed, as it were, with a wave of the hand, and no time need be given here to a consideration of them. Compound skull fractures, serious hemorrhage, either intra- or extra-cranial, and fractures with depression of fragments are, of course, real surgical problems and often require operative intervention. In head injuries as a class, however, we are not concerned so much with what happens outside the skull or to the skull itself as we are with what actually happens to the brain and its coverings. For this reason, we herewith adopt as a premise the fact that all head injuries have a neurological aspect and that the greater percentage of them belong primarily in the neurological field of medicine.

In our consideration of what actually happens to the intracranial contents in a head injury, we must remember two vitally important facts:

1. A very bad brain injury may occur without a fracture of the skull.
2. Extensive skull fractures may take place without any actual injury to the brain or its coverings.

The occurrence of either of these two does not necessarily signify the existence of the other.

Let us then try to visualize what may occur, intracranially, in a head injury. Protected as it is, within the skull, by its membranous coverings and the cerebrospinal fluid, the brain is able to withstand, to a remarkable degree, trauma applied to the skull. The effect on the brain must necessarily depend upon the degree of trauma, the method and point of its application and the particular circumstances during and after the accident. The first notable thing that happens is what we term concussion. Various definitions of concussion have been devised such as "molecular disturbance of brain cells resulting in loss of consciousness," etc. Symonds, of London, in the British Medical Journal of November 10, 1928, defines concussion as "a condition of sub-total cessation of cerebral function following immediately upon the injury and lasting only a few moments, with subsequent complete recovery within twenty-four hours." He assumes that unconsciousness or a clouding of consciousness which persists for more than this length of time is not concussion, but is evidence of structural brain injury. We subscribe to the belief that concussion itself may last longer than twenty-four hours, and we designate, arbitrarily, various degrees of concussion, as follows:

1. Slight concussion, in which unconsciousness or clouding of consciousness lasts from a moment up to one hour.
2. Moderate concussion, in which normal consciousness remains absent for a period up to twenty-four hours.
3. Severe concussion, in which consciousness is absent or clouded for a period greater than twenty-four hours.

In any event, we believe that concussion itself does not necessarily imply structural brain or intracranial injury, and likewise that the absence of a true concussion does not eliminate structural injury to the cranial contents. Hemorrhage into the brain itself and into the subarachnoid space, with bruising or contusion and actual laceration of the brain itself, are far more frequent in head injuries than is commonly believed. The delicate structure of the brain, the highly specialized and organized system of blood vessels serving it, and its relationship to the membranes which cover it and to the bony structure which houses it, make it very vulnerable as far as minor injuries to it are concerned.

---

*Thesis presented before the Minnesota Academy of Medicine, November 12, 1930.

If we accept Trotter's explanation of concussion, we may assume that with sudden severe trauma the skull acts as a semi-elastic body and is momentarily compressed, so that its contents are squeezed dry. Unconsciousness and a flaccid paralysis of the body follow, as a result of the sudden cerebral anemia. Recovery of consciousness takes place through a gradual return of physiologic function from the medullary centers progressively upward, so that the whole clinical picture is one of temporary vascular embarrassment. In addition to the above, if the trauma is severe enough or is applied at the proper point, we have a shaking up of the brain and its coverings, with bruising or contusion or lacerations and with hemorrhage of greater or lesser magnitude, with petechial bleeding in the substance of the brain itself, intraventricular hemorrhages or subarachnoid bleeding due to rupture of meningeal vessels. Any such clinical picture as the above results in immediate edema of the brain with increase in intracranial pressure due to fluid increase. Such a condition may result in a markedly prolonged period of lost or clouded consciousness, due solely to increased intracranial pressure instead of true concussion or structural brain injury.

Illustrative of this is the case of B. E., a little girl eight years old, who was seen in consultation with Dr. Albert Ahrens of St. Paul, about two years ago. This child had been knocked down by an automobile and when first seen had been totally unconscious for three or four days and remained very clouded for ten or twelve days more. At the time we first saw her, she lay in a semi-stupor; was unable to swallow, her sensorium was completely obliterated, and although her eyes were open there was absolutely no true consciousness present. She had been fed with a tube all of the time since her injury. A spinal puncture showed a clear fluid under greatly increased pressure. The first drainage resulted in immediate cerebral improvement, and several subsequent spinal drainages cleared her completely in a few days, improvement being noted after each one was done.

A second illustration may be given in the case of a man referred to us from Menomonie, Wisconsin, four or five years ago, who had sustained a severe concussion by being thrown from a railroad train, his head striking the base of a telegraph pole. Although he sustained a concussion, he cleared very shortly and was referred to us some ten or twelve days after the accident, because of headache, vertigo, sluggish mental reflexes and personality changes. Examination showed no focal signs of brain injury, and neurologically there was no evidence of any structural injury to the brain. His eyegrounds, however, showed marked evidence of increased intracranial pressure. Assuming that this man had a wet brain following the accident, he was sent to the hospital and daily spinal drainage was performed for some five or six days, the fluid being clear but under marked increase in pressure. Following each drainage, there was relief, both subjectively and objectively, and at the end of ten days or two weeks he had completely regained his normal personality; his mental reflexes had become normally active, his vertigo and headache had disappeared and his eyegrounds had returned to a normal condition.

In addition to the injuries already enumerated, we often have the exhibition of cranial nerve lesions following head trauma. These may be due to nuclear injury, such as hemorrhage or contusion, or they may be due to injury to the nerves themselves after they leave the base of the brain on their way to the exit from the skull. The latter occur notably in basal skull fractures and in severe subarachnoid hemorrhage, particularly at the base. These cranial nerve lesions are valuable from the standpoint of diagnosis and localization, and are temporary or permanent, according to the location and degree of the injury. It must be remembered that hemorrhage by "countre coup" is a frequent and often undiagnosed factor in head injuries. In attempting localization, this possbiility should ever be borne in mind.

Passing on, we will undertake to consider, from the angle of the neurologist, the immediate treatment of the head injury, assuming that no operative condition exists, and confining our observations to the intracranial condition. If concussion exists, with a rapid return of normal consciousness, and no signs of focal injury or intracranial hemorrhage, no particular treatment is indicated other than absolute rest for a day or two, with relief of subjective symptoms as they may arise. If unconsciousness or a clouding of consciousness persists, a careful and complete neurological examination is indicated, with very close observation of the patient's condition from one hour to another. The examination is directed toward localization of any intracranial injury and toward the condition of intracranial pressure. To these ends particular attention is paid to cranial nerves and to reflexes in the extremities, to the eyegrounds, the pulse, the temperature, the respiration and the blood-pressure. Careful note is also made of the condition of the individual's sensorium. We believe spinal puncture to be valuable from the standpoint of diagnosis as well as treatment, and we use it unhesitatingly and have never seen it do any harm. The occurrence of bloody spinal fluid proves conclusively subarachnoid or intraventricular hemorrhage, assuming, of course, that the fluid is uniformly bloody and not merely blood-tinged in the first few drops where the needle strikes a vessel in the operation of puncture. Likewise, subsequent punctures reveal the condition of the hemorrhage—a gradual daily fading in the coloring of the fluid showing that the hemorrhage has ceased.

From a therapeutic point of view, drainage of the canal reduces the fluid intracranial content and relieves increased intracranial pressure and frequently promotes rapid clearing of consciousness. It has been our observation that this is particularly true in those cases as cited above, where consciousness has partly returned but is cloudy and in which there is no paralysis or other evidence of focal brain injury. We have several times seen a marked benefit rendered to paralyzed cranial nerves by repeated spinal drainages. Repetition of the drainage is made in direct accord with the degree of increased pressure of the fluid which is observed. It is frequently repeated every twelve hours; in other instances every twenty-four to forty-eight hours, as the individual case seems to warrant. There is no definite rule as to frequency of drainage or amount of fluid withdrawn. Each case determines its own status in these respects. We believe in spinal drainage in proper cases; we advocate it and we prefer it to the use of saline or magnesium sulphate.

Miss M. R., a patient seen with Dr. Carles N. Hensel, of St. Paul, in the winter of 1928-1929, is an example of the large number of cases in which spinal drainage has shown itself to be definitely valuable. Knocked down by an automobile and sustaining an apparent slight concussion, with laceration of her scalp, she was taken home, walked into her house and up two flights of stairs to her bedroom, and a short time later collapsed again unconscious. We saw her about two and one-half hours after the injury was sustained. Her consciousness was very clouded. She had a marked sensory aphasia and was in very poor condition generally. Diagnostic spinal puncture showed bloody spinal fluid, under markedly increased pressure. A full drainage was done and repeated at twelve hour intervals several times, with marked improvement after each drainage. This patient subsequently recovered, uneventfully, except that she has permanent loss of sense of taste and sense of smell. The aphasia did not persist. In this particular case, the bloody spinal fluid did not clear at once, several successive punctures indicating the presence of fresh blood. This fact, together with the marked increase in pressure shown at each puncture, is, to our mind, evidence that the constant intracranial bleeding would probably have killed this patient had not the pressure been relieved at intervals by spinal drainage. It has been our observation that there is a better prognosis in severe head injuries which present a bloody spinal fluid under greatly increased pressure than in those where the fluid is clear and under normal or reduced pressure.

Careful observation during the first thirty-six or forty-eight hours after injury often permits the early diagnosis of concealed or delayed intracranial hemorrhage, with focal symptoms such as paralysis of one kind or another or a second gradual loss of consciousness. It is in this class of cases where operative intervention is often most valuable.

A patient seen with Dr. L. E. Daugherty, in St. Paul, in the winter of 1929, had been injured by a collision between his car and a railway train. He was taken unconscious to a hospital, regained consciousness shortly, and seemed to be all right in every way. Within a few hours, however, he began to notice motor disturbance in one of his lower limbs, which gradually progressed to a complete paralysis, with reflex changes of the upper motor neuron type, and with a clouding of the sensorium which finally reached total unconsciousness. Operative intervention was advised following localization of the hemorrhage and a decompression, performed by Dr. Harry P. Ritchie, disclosed a subdural clot of considerable size, which was removed, and the patient recovered fully.

Most important and often most difficult is the task of determining permanency in head injuries and of deciding which of the existing sequelæ will never be relieved. No hard and fast rule can be applied in making such tests. Each case must be studied as an individual problem and classified accordingly. There are, however, certain definite after-effects which are commonly found in head injuries and which can be looked for quite uniformly in all cases. The remote effects of these injuries are most important from the industrial and medico-legal angle, and it is well to give them a prominent place in this discussion. To begin with, we must classify these symptoms very positively into subjective and objective. Among those predominating in the subjective group are the following:

1. Headache
2. Vertigo
3. Nausea
4. Inability to concentrate normally
5. Failure of memory
6. Emotional disorders, such as depression, fear and anxiety
7. Premature fatigability.

Among those prominent in the objective group are:

1. Paralyses of various kinds
2. Vomiting
3. Reflex changes
4. Inability to sleep
5. Marked loss in weight
6. Crying spells
7. Spells of intense emotional disorder
8. Aphasia or amnesia.

Without attempting to treat each of these singly, but grouping them for consideration, it can be stated first that the average case of head injury presents far more subjective than objective symptoms from the standpoint of sequelæ. One naturally expects, after a head injury of sufficient magnitude to produce concussion, that there will be for a time an exhibition of many or all of these after-effects. As to just how long they will last, however, is a matter of opinion, based largely on experience and circumstances surrounding the individual case.

Of the subjective sequelæ enumerated above, the most persistent are headache, inability to concentrate normally, and premature fatigability. Under ordinary conditions, it will be conceded that six months is sufficient time to heal a simple skull fracture without depression of fragments, no matter where this is situated. The various subjective symptoms usually disappear, in irregular fashion, in from three months to one year after the injury, depending upon their severity. The resistance of the individual and the speed with which litigation and questions of compensation and damages are settled are very important factors in determining the length of time required for such symptoms to disappear. The last is of paramount importance. Regardless of how the settlement is made or of how favorable or unfavorable to the injured person it may be, the fact that the case is settled and out of the way is always beneficial and expedites recovery. The facing of a law-suit, with the inevitable anxiety attendant to it, and the necessity of keeping all facts in mind to recite to the jury, is a great obstacle to recovery.

As to the objective symptoms, it may be stated briefly that those symptoms which persist for more than one year will probably be permanent. It is surprising how many abnormal reflexes will adjust themselves to normal in the course of twelve months after an injury and how many objective signs and symptoms will disappear during that length of time. Here again, of course, the individual case must be taken into consideration, but, in general, permanency is reached after a year has elapsed, and those sequelæ persisting that length of time may be considered as permanent. Again, in the consideration of sequelæ, particularly those in the subjective group, the age of the individual is most important as far as prognosis is concerned. We have had under our observation, at intervals, a detective who was slugged in a jewel robbery a few years ago, having been knocked out by a black-jack in the hands of the highwayman, and sustaining thereby a stellate fracture of the outer table of the skull, in the parietal region. He was unconscious only a few moments and there were no focal signs and no intracranial complications. Neurological examinations have been repeatedly negative, and nothing objective has ever been found, yet he has never been able to work a day at his regular profession with the Pinkerton Agency since he was hurt. Sixty-two years old when injured, he has never been able to regain his normal power of concentration at his work, cannot follow instructions accurately and cannot make out ordinary reports. In addition, he is depressed and somewhat upset emotionally. Were he twenty or thirty years younger, he probably would have recovered long ago. As it is, he will doubtless never work again at his regular employment.

Conversely, a young man of twenty-seven, recently seen, who sustained a very severe head injury in the crash of the Northwest Airways plane last year, receiving a severe concussion with multiple skull fractures, and an evidently profound cerebral disturbance, will probably recover his normal efficiency and be able to go on with his regular work. He presents the same clinical picture, subjectively, as the first mentioned case, but has the advantage of being young and in the constructive period of life. Thus it is seen that a multiplicity of factors must govern the permanency of after-effects in head injuries, but in a general way it may be reiterated that the majority of those who recover fully do so in one year's time.

Statistically, it is difficult to state positively what percentage of head injuries becomes permanently disabled or recover fully. An analysis of seventy-one cases, by Symonds, in which he had secured accurate data at periods remote from the accident, shows 10 per cent totally disabled, 43.5 per cent able to return to light work, and 46.5 per cent able to return to full work. These seventy-one patients were individuals who had sustained definite cerebral disturbance following head injury.

One cannot leave this subject without a word in comment upon mental deterioration and epilepsy, as sequelæ of head injuries. As far as the former is concerned, we believe that genuine mental impairment following head injury is comparatively infrequent. So-called mental deterioration or feeble-mindedness in children, which for purposes of litigation is frequently attributed to some head injury sustained early in life, usually turns out to be ordinary congenital mental deficiency. Permanent mental impairment or deterioration to the extent of requiring institutional care is certainly rare.

Epilepsy as a sequel of head injury is often a matter of dispute in the court room and a matter of difference in opinion among medical men. Briefly, it may be said that the only kind of epilepsy which follows head injuries is the Jacksonian type. This is always due to focal brain injury or irritation. Epileptic spells may occur in the early stages of a head injury and are probably due to hemorrhage into the subarachnoid space, and do not always mean a permanent likelihood of attacks. Jacksonian epilepsies, developing after a period of many months or years after the injury, are much more serious. Essential epilepsy, in any form, is never caused by head injury, and as a rule if the Jacksonian type of spells are going to occur, they usually make their appearance within a reasonable period of time after the injury, probably within six months. If they appear at an interval more remote than that, they are usually due to cyst formation, abscess or some degenerative lesion, which takes time to develop.

The subject of head and brain injuries is one of profound interest and importance. As stated in our opening paragraph, we believe it to be largely neurological. Certainly, it is deserving of the consideration of every member of the medical profession.

TREATMENT OF SECONDARY DEFORMITY IN CASES OF HARELIP*

GORDON B. NEW, M.D., AND FREDERICK A. FIGI, M.D.
Rochester, Minnesota

AT THE present time, the results from operations on harelips by those experienced in this type of work are excellent in a large percentage of cases. There are, however, a certain number of cases in which operations have been performed by inexperienced surgeons, and secondary deformities have resulted which require correction (Fig. 1*a* and *b*). Such deformities may not be the result of the operation but may be due to the fact that the child was in poor physical condition at the time of the operation or that the wound became infected. In these cases a careful general examination should be made, and, if necessary, the patients should be observed carefully until their condition is such that operation is advisable. As a rule, the results from operation for harelip are much better during the spring, summer and autumn than during the winter, on account of the tendency to upper respiratory infections with running of the nose. We operate in winter only on children who cannot be brought to us at any other time. The use of silkworm-tension sutures to hold the ala in position and of a Logan clamp to relieve the tension on the suture line are both invaluable aids in preventing secondary deformity, regardless of the method employed.

The deformity may be of a minor nature, such as slight flaring of the nostril, or notching or irregularity of the vermillion margin, but such deformities detract from an otherwise good result and are noticeable. At times one sees such deformity as slight flattening of the upper lip due to approximation of the alveolar process by wires, or the more marked deformity due to the loss of the greater portion of the upper jaw from a disastrous attempt forcibly to approximate the jaw. The marked flattening of the upper lip resulting from the removal of the premaxilla is a common deformity. Secondary deformity presents greater problems in correction than the original condition on account of the loss of tissue and the scarring (Fig. 2*a* and *b*).

The aim of the surgeon when he accepts for operation a patient with a single harelip should be to make the nose and lip so shaped that the average person would not know that a deformity had existed. To accomplish this ideal means that many secondary operations must be performed, some of which, however, may be of a minor nature.

A common postoperative deformity in cases of single harelip is the displacement of the median line of the nose to one side with rotation of the tip of the nose and flaring of the nostril. There is also frequently notching or irregularity of the vermillion margin. In such cases the long axis of the oval-shaped vestibule of the nose on the harelip side is usually directed laterally instead of anteroposteriorly. This deformity is usually the result of incomplete freeing of both cheeks and nose at the time of the operation, and not rotating the tissue below the ala of the nose into the nostril to form the floor, as Blair has shown. It is well to make a nostril a little smaller and the outer extremity of the ala a little higher than the opposite side at the time of the operation, as there is always a tendency for the spring of the cartilage to cause the ala to displace outward and downward (Fig. 3*a* and *b*).

The correction of this deformity usually requires thorough freeing of the lips, cheeks and cartilage of the nose, and possibly refracturing of the nasal bones to bring the nose to the median line and fix it in this position with sutures or splints. To change the oval-shaped opening of the vestibule of the nose so that the long axis is anteroposteriorly instead of laterally a triangular wedge of cartilage is excised from the anterior part of the columella below the tip of the nose, and, by rotating the cartilage forward and inward, correcting this deformity. Fixing the cartilage and ala in its new position by means of silk sutures and silkworm-tension sutures is essential. The ends of the silkworm sutures are fixed by lead buttons and shot. In order to allow the flared ala to be brought into its correct position without folding, it is sometimes necessary to free the skin and mucous membrane from the cartilage so that the cartilage will slide between the skin and the mucous membrane, or to crosshatch the cartilage at certain points to eliminate the curve. In this type of deformity it may be necessary to remove a piece of the cartilage from the margin of the ala and the tip of the nose, as this is usually lower than the remainder of the nose, due to its rotation (Fig. 4*a* and *b*).

---

*From the Section on Laryngology, Oral and Plastic Surgery, The Mayo Clinic, Rochester, Minnesota. Submitted for publication January 7, 1931.

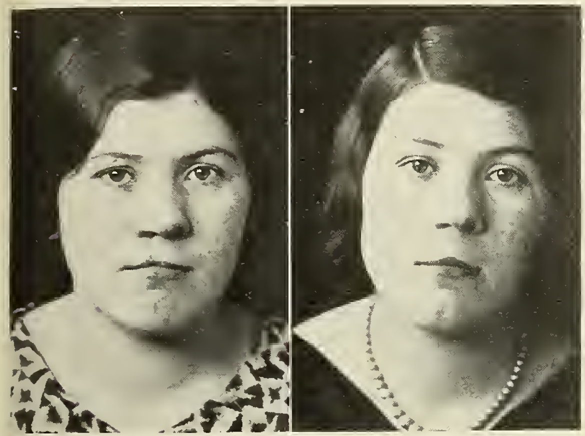

Fig. 1. *a,* Flared nostril with notching and irregularity of the vermillion margin; *b,* deformity corrected by rotating inward the ala with the area of skin below it to form the floor of the nose; excision of the scar and realignment of the vermillion margin.

Even after correction of the remainder of the deformity, as outlined, there still may remain a flattening of the side of the nose, the result of lowering and rotation of the tip. Although it has been suggested that this alar cartilage, which is usually concave externally, may be removed and replaced with its convex surface outward, we feel that the insertion of cartilage, either from the back of the ear or from the rib so that it just fills this flattened area, producing fullness comparable to that on the opposite side, is preferable.

In the cases in which deformity of the nose is associated with double harelip there is usually more marked deformity than in the cases of single harelip (Fig. 5*a* and *b*). Rounding of the bridge and tip of the nose, flattening of the anterior part of the vestibules, and shortening of the columella are characteristic. If the patient is a child this is best corrected by advancing the skin over the nose and lengthening the columella; if an adult, the cartilage in the region of the tip should be readjusted to stand forward as a tip. It may be necessary to remove a part of the nasal bone in order to correct the rounding of the bridge.

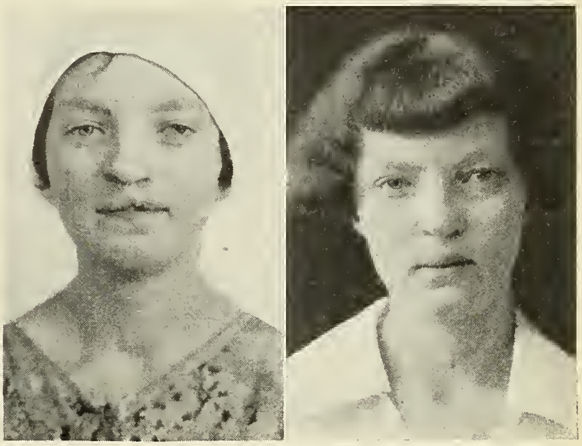

Fig. 2. *a,* Displacement of the median line of the nose to the right, with flared nostril, rolling of the margin of the ala and notching of the vermillion margin; *b,* the position of the nose in the median line; the deformity of the ala and vermillion margin has been corrected; the flattening of the left side of the nose has been corrected by means of a cartilage implant.

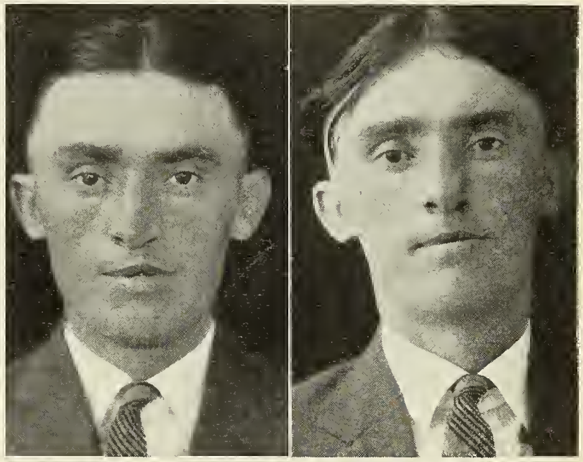

Fig. 3. *a,* The median line of the nose is displaced laterally; the lip is short and the vermillion margin is drawn up; *b,* the nose has been placed in the median line, the deformity of the lip and ala corrected, and the vermillion margin realigned.

The lip in most of these cases of postoperative deformity has to be lengthened or shortened, and the drawing up of the vermillion margin with notching corrected. The lip may be lengthened by making concave incisions, removing the scar down to a point laterally on the vermillion margin and then reapproximating the lip. In cases of double harelip the usual deformity of the lip is too much length from the columella to the vermillion border, and it may be necessary to remove a part of the tissue to correct the deformity. The vermillion margin may have to be rolled out on both sides and sometimes reconstruction of an entire new vermillion margin is necessary because of rolling out of the mucous membrane from the inside of the upper lip. If the nose and lip are scarred down to the jaw and the alveolar process, the use of Thiersch grafts on dental compound after excising this scar may be necessary to raise the nose and the lip. In older children and adults a dental plate may be used to fill in this newly formed pocket and to hold the nose and lip forward.

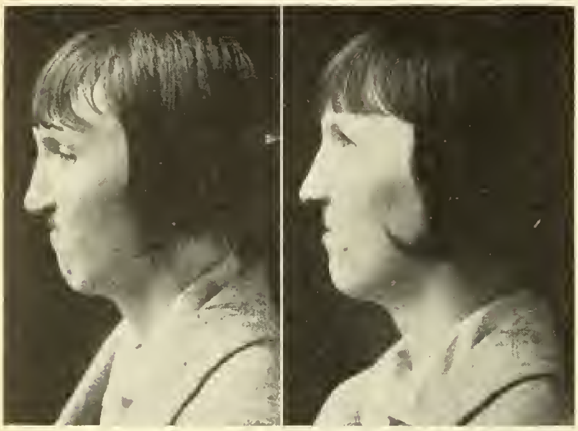

Fig. 4. *a,* Typical lateral view of patient with flattening of the upper lip, the result of forceful approximation of the alveolar process; the cartilage at the tip is lowered from the rotation of the nose; *b,* correction of the deformity, removal of the cartilage and insertion of a dental plate to hold the upper lip in correct position.

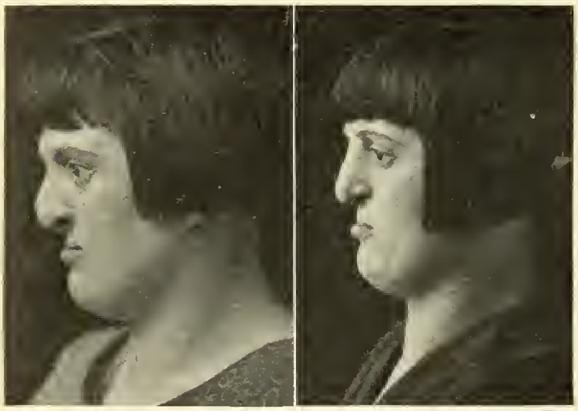

Fig. 5. *a,* Deformity resulting from double harelip; the rounding of the bridge and tip of the nose, with a short columella and upper lip, and the flattening of the upper lip may be seen; *b,* the lip has been lengthened, the cartilage of the tip of the nose has been readjusted so that a tip has been made, the hump has been removed and the columella lengthened; further removal of an elliptical piece, and rolling the lower lip inward would further correct the deformity.

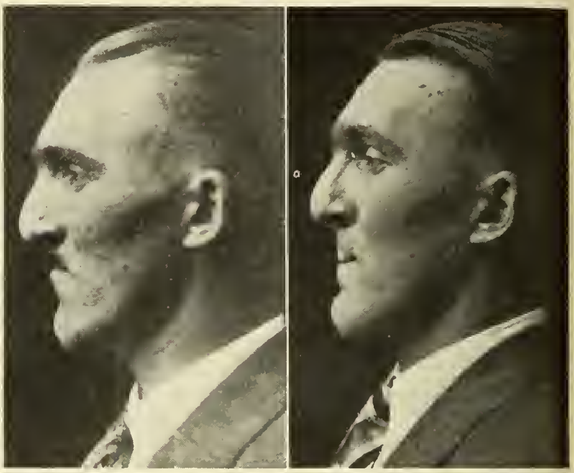

Fig. 6. *a,* Double harelip with loss of the premaxilla and part of the upper jaw; the upper lip is flattened and shortened; *b,* the loss of tissue in the upper lip has been replaced by turning up on a lateral pedicle a wedge-shaped piece from the center of the lower lip; rounding of the bridge of the nose should further be corrected.

The upper lip may be short laterally, due to loss of skin and mucous membrane from repeated operations. In this type of deformity a wedge-shaped portion of the full-thickness of the center of the lower lip is turned up on a lateral pedicle. The flap from the lower lip is sutured in the median line of the upper lip after excision of the scarring. It is necessary to feed the patient for about two weeks by means of a tube or catheter until the pedicle may be cut across and the suturing completed. This makes a satisfactory replacement of the skin and vermillion margin of the center of the upper lip. The deformity due to loss of the premaxilla and anterior part of the upper jaw is best corrected by means of dental appliances which hold the lip forward (Fig. 6*a* and *b*).

The correction of these secondary deformities usually requires much patience and ingenuity and sometimes multiple operations. Whether the deformity is small or great, it behooves the surgeon to do everything possible to correct it.

CARDIAC EMERGENCIES*

John M. Lajoie, M.B. (Tor.), M.D.
Minneapolis

IN AN organization like this Clinical Club, where each member is limiting his work to some special domain in medicine, all do not have the time or opportunity to become familiar with he various cardiac emergencies that may arise. I thought it would be of interest to review these alarming conditions. It has been a great help to me at times to quickly consider in tabloid form the various types of cardiac emergencies while getting ready to do something when face to face with a more or less alarming emergency.

First of all it is well to remember that symptoms of sudden onset referable to the heart are not necessarily associated with structural disease of that organ. I have in mind a woman I had in the hospital under treatment for a cardiac condition. She was very nervous and suddenly developed a sinking sensation in the region of the heart. She thought she was dying and sent for me and her family. When I arrived she was lying flat in bed with her eyes fixed and looking beyond the ceiling, her family were about her and everything suggested the approach of death. The skin was warm, the breathing was quiet and shallow, the pulse and blood pressure were normal and the heart showed no change. After I succeeded in assuring the family and the patient that death was not hovering about they all had a little laugh about the affair and the family went home.

In functional heart conditions the circulatory failure is not associated with any constant change in cardiac morphology. We are afforded help by the changes that occur in the circulation in parts of the body other than the heart. These changes help us to recognize the functional basis.

The exact nature of the changes in the dynamics of the heart which underlie the signs and symptoms of heart failure are as yet not clearly understood.

In a general way heart failure may be divided into two kinds: one in which the left side gives away functionally, and the other in which the signs and symptoms indicate that the right heart is affected. Failure of the auricles does not produce alarming symptoms, and there are many persons going about in apparently good health with their auricles functioning poorly.

The important symptoms present in left heart failure are: cough, usually worse at night, Cheyne-Stokes breathing, attacks of cardiac asthma and acute edema of the lungs. The physical signs that may be present are râles in the base of the lungs and difficult breathing. There are signs also of the underlying cause of the left heart failure, as hypertension and chronic nephritis, arteriosclerosis and luetic aortitis.

Very much different are the signs presented in right heart failure. They are cyanosis, pain and tenderness in the region of the liver, an enlarged congested liver, edema and effusion of the serous sacs, and scanty urine.

As an example of left heart failure may I call to your attention a patient I have under management for decompensation at the present time (C. E. T.). The patient has an aortic insufficiency due to lues, with the valves involved at their commissures near their attachment to the aortic wall. When there is evidence of aortic insufficiency one should always suspect syphilis. I will go further and say that if a person of middle age becomes decompensated for no apparent reason we must suspect syphilis.

As an example of right heart failure I will cite the case of a woman (Mrs. N. C.) who when first seen had a chronic heart condition, marked edema, cyanosis, ascites, large tender liver and scanty urine. Prompt paracentesis was indicated and done and followed by the usual cardiac management. The heart improved, the large liver became smaller, the urine increased but the ascites persisted, requiring paracentesis some ninety times. The tenderness and pain in the region of the liver was due to the acute stretching of the liver capsule, and is a very important early sign of failure of the right ventricle. Tenderness in the epigastrium and right hypochondrium may occur even before the liver is large enough to be palpable. Later, as the liver becomes chronically enlarged, the pain subsides and the liver becomes filled with connective tissue.

---

*Read before the Minneapolis Clinical Club, October 9, 1930.

Scanty urine is of more importance than albuminuria in indicating passive congestion of the kidneys. The edema that occurs in right heart failure tends to gravitate to dependent parts and it may disappear, but ascites and pleural effusion persist.

In auricular fibrillation the high auricular rate is the cause of the sudden circulatory embarrassment. In this condition the urgent need is to remove the load by slowing the ventricular rate. This is best accomplished by giving large doses of digitalis. A hypodermic of morphia helps to put the patient at ease and give much needed rest. It is a life-saver when the patient is so distressed he cannot remain in bed. I saw such a patient (Mr. P. D.) in consultation last year. He had auricular fibrillation and was so badly decompensated that he could not stay in bed. He had been in a chair for four days. Morphia for forty-eight hours made him comfortable in bed and with sufficient digitalis he improved so rapidly that he was symptom-free in a short time and has been about and apparently well ever since.

Besides proper medication, absolute rest, a simple light diet, restricted fluids and active purgation are indicated. Digitalis is of doubtful value in urgent cases of congestive failure with increased rate if the rhythm is normal. If done very early, venesection of ten or fifteen ounces of blood helps by lowering the pressure. If there is no digitalis in the system an intravenous injection of strophanthin gr. 1/250 in 40 c.c. of normal saline may be of benefit.

Auricular flutter illustrates a condition where the amount of blood put out by the heart has been shown experimentally to be diminished. In this condition the blood pressure is low, there is cyanosis and weakness. Since this is a shock type of failure, digitalis perhaps does more harm than good. It should be remembered, however, that digitalis is sometimes used in auricular flutter to change the rhythm responsible for the failure and not to treat the failure itself.

Mitral stenosis is a type of heart failure which has for its chief characteristics the inability of the heart to increase its output sufficiently to meet the ordinary demands of the body. The essential treatment is to limit the activity of the individual. Digitalis is of benefit if not depended on too much. It slows a fast heart, allowing the left ventricle to fill more completely during diastole and its stimulation of the left ventricle aids the peripheral circulation.

The advanced hypertensive heart is a type of heart failure which shows no evidence of any diminution of the cardiac output. The chief symptom is dyspnea occurring at night or after exertion. The blood pressure is high, the pulse full, the color is good and the extremities are warm. The symptoms do not suggest shock. In a hypertensive heart the ability of the right and left chambers to adjust their work to rapidly changing demands may be diminished so that the right and left ventricle do not coöperate well. When a call for increased work comes to such a heart the left ventricle is unable to respond. The right ventricle being able to respond increases its output so that a temporary congestion of the lungs follows this response, resulting in an attack of dyspnea. A hypodermic of morphia quiets the patient and perhaps reduces the cardiac output allowing normal coöperation between the right and left ventricle. Atropine should not be used as it increases the heart rate. Digitalis, if used, may diminish the frequency of attacks.

This brings us to acute edema of the lungs. The coughing of blood-stained serous fluid is indicative of very serious trouble in the pulmonary circulation. At the onset a small dose of morphia and 1/100 of atropine should be given. If there has been delay in giving the morphia and atropine, venesection of from fifteen to twenty ounces of blood is the only treatment likely to benefit the patient. When acute pulmonary edema is not due to cardiac insufficiency or to a pneumococcus or a streptococcus infection it may be due to localized angioneurotic edema or to some local vasomotor disturbance.

There is a paroxysmal dyspnea of cardio-renal patients that has the habit of occurring at night and is very alarming. If signs of respiratory infection are present, such as a bronchitis, the use of bronchial sedatives with inhalations will be very welcome to the patient. But if the patient is having Cheyne-Stokes type of breathing and shows no greater distress while lying flat than when propped up with pillows the breathlessness is due most likely to an acidosis due to the retention of renal insufficiency. Here again morphia will give immediate relief. A course of diuretin and three or four weeks in bed is the treatment to be carried out.

Another very alarming condition is one due to an embolism. When an embolism plugs a vessel carrying blood to the lung or one supplying the brain the symptoms produced are the result of the changes of the vascular supply to the infarcted area. When a clot is detached from the right auricular wall of a fibrillating heart it may lodge in the pulmonary vessel and cause dyspnea, hemoptysis, pleuritic pain and later pleural effusion, but, if the mural thrombus is from the left auricle the signs will be those of cerebral embolism or the occlusion of some other artery. Morphia should be used to relieve the distress and to insure complete rest. If pleuritic pain develops the affected side should be strapped with adhesive.

Cardiac syncope.—This is a sudden attack of unconsciousness which may be terminal, in which case treatment would be of no avail. Cardiac syncope may occur in persons who are apparently in good health. It may be caused by a plugged pulmonary artery, the occlusion of a coronary artery, or a ruptured ventricle or aortic aneurism.

There is a much larger group of cardiac patients who have less serious symptoms. In this group the syncopal attack is due to a sudden disturbance of the normal cardiac mechanism which results in a diminished cardiac output and low blood pressure which in turn causes a lessened supply of blood to the brain. These attacks are believed to have their origin in some disturbance of the vagus nerve and recovery is spontaneous when the vagus releases its control of the sinoauricular node. In this condition atropine in large doses is useful.

Another cause for a syncopal attack is the onset of complete heart block. Among the causes of heart block may be mentioned arteriosclerosis, syphilis, rheumatism and the improper administration of digitalis. The underlying condition should be sought and, when found, its proper treatment should be undertaken. It is well to remember that patients do not die from the conditions peculiar to heart block; they die from heart failure. The conduction changes resulting in heart block are sometimes produced by the vagus and a long interval of freedom from attacks may be obtained by the use of atropine. When there is complete auriculo-ventricular dissociation the syncopal attack may be controlled by intramuscular injections of adrenalin hydrochloride, which increases the rate and strengthens the contractions of the ventricle. Barium chloride, 30 mg. four times daily, has been used. It acts by increasing the irritability of the auricular ventricular bundle, and by raising the ventricular rate prevents standstill. I am not very enthusiastic about its use.

Digitalis may convert an incomplete block into a complete block, and therefore should not be used. But if a complete block exists, digitalis may be helpful. The presence of a Stokes-Adams syndrome is the only contraindication to the use of digitalis in complete heart block.

I wish to mention some other conditions in which syncope occurs as the result of diminished cardiac output and low blood pressure. I refer to paroxysmal tachycardia with a heart rate from 160 to 180 beats per minute and to auricular flutter where the auricular rate varies from 200 to 350 beats per minute. When the rate is so fast, the associated fall in blood pressure causes a diminished supply of blood to the brain and syncope. When the greatly increased rate is due to paroxysmal tachycardia, gradually increasing pressure on the right vagus nerve as it courses along the carotid sheath is effective in aborting many attacks. If the attack is of ventricular origin digitalis may help. I have seen quinidine used with apparent success. Auricular flutter, which is rare, may be the cause of the increased rate. It differs from true paroxysmal tachycardia in that the increased rate is practically always associated with failure of conductivity; *i.e.,* it is a two to one heart block. A persistent ventricular rate above 120 in elderly persons presupposes auricular flutter. Full doses of digitalis are used to change auricular flutter into auricular fibrillation and finally into a normal rhythm.

A very alarming emergency that happens too often in the operating room is that of cardiac arrest. It is unsuspected and unforeseen. Cardiac arrest in the operating room is either primarily cardiac or secondary to vasomotor relaxation. Cardiac failure secondary to vasomotor relaxation may be suspected by frequent blood pressure readings during anesthesia. By intravenous injections of fluid the pressure may be maintained and cardiac arrest prevented. If cardiac arrest has occurred one must work quickly and restore cardiac rhythm before six minutes has elapsed. The success of treatment usually depends on the operating room staff being ready for the emergency. First give a solution of 1-50,000 adrenalin in normal saline into the left common carotid artery. Give about 200 c.c. If this fails an osteoplastic flap made through the chest wall will allow the operator to do cardiac massage, which is successful in about 25 per cent of the cases. It is well to remember that cardiac stimulants are rarely successful if the circulation has ceased.

Both types of cardiac arrest are probably associated with ventricular fibrillation.

Of all the causes of cardiac syncope none compare in seriousness with that of fibrillation of the ventricle. It is a terminal event and there is nothing we can do to help the patient. It is the cause of death in early chloroform anesthesia. It may terminate a Stokes-Adams syndrome. It occurs in persons taking digitalis or quinidine, and it may occur in apparently healthy persons. This emergency may never arise if we keep it in mind and are careful. Digitalis should be discontinued in treating auricular fibrillation if there is a slow bigeminal pulse. Strophanthus should not be given intravenously in larger doses than gr. 1/250 in a twenty-four hour period and should not be given at all if there is digitalis in the patient's system. Quinidine should be reserved for selected cases which are at rest in bed and under careful observation.

There are some other forms of shock having cardiac signs or symptoms. They are the heart failures that occur in acute infections and those associated with pregnancy. Since they are not associated with any definite pathological condition and are not primary heart conditions nothing more will be said about them.

In conclusion, since we now have on our finger tips the various forms of cardiac emergencies, there will be times when there may be some doubt in our minds as to the correct diagnosis and the best remedy to employ. While making a mental study of the presenting symptoms we can be of help if we keep in mind two important factors: namely, to establish self-control and confidence in the patient, and to bring about spontaneous relaxation following exhaustion. To quiet the nervous system and relax the spasm nothing is so helpful as a hypodermic of morphia and atropine. The atropine is used to prevent depression. Have the patient recline on some pillows. For quick momentary action smelling salts serves a purpose, or a tablespoonful of whisky in twice the amount of hot water. Hot coffee by mouth, if the patient can take it, is excellent, and may also allow the belching of gas. If collapse, dyspnea, low blood pressure or cyanosis is present, ergot may be injected into the muscle with good results.

In closing may I say a few words about digitalis, our best heart remedy? It was first brought to the attention of the medical profession by Withering in 1785. Its best therapeutic effect is obtained by using the standardized tincture which combines all the qualities of the various isolated principles. When digitalis is employed in therapeutic dosage where there is a disturbed cardiac mechanism it produces decreased conductivity of the auricular ventricular node, causing a slower pulse, and it increases the force of the ventricular contraction. In other words it lengthens and strengthens cardiac systole, causes an increase in pulse force and raises arterial pressure.

No definite limit can be placed on the amount of digitalis necessary to produce and maintain a desired physiologic result. When the drug is given in large doses it is essential that the patient be carefully watched and that it be discontinued on the appearance of symptoms of physiologic intolerance concerning which Withering said, "Let the medicine be continued until it either acts on the kidneys, the stomach, the pulse or the bowels; let it be stopped upon the first appearance of any one of these effects."

DIFFERENTIAL DIAGNOSIS OF ENDOCARDITIS*

Harry L. Smith, M.D.
Rochester, Minnesota

THE clinical types of endocarditis may be subdivided as follows: (1) acute bacterial endocarditis, (2) subacute bacterial endocarditis, and (3) rheumatic endocarditis: acute rheumatic endocarditis, recurring rheumatic endocarditis, and chronic rheumatic endocarditis.

In the majority of cases, when a diagnosis of endocarditis is established, the particular type is not difficult to determine. This is especially true of the typical cases (Table 1); in the atypical cases considerable difficulty is encountered at times in differentiating the types.

Subacute bacterial and acute and recurring rheumatic endocarditis are the types that are likely to be confused, and they cause the most difficulty in diagnosis. Occasionally, a fulminating type of subacute bacterial endocarditis will closely resemble acute bacterial endocarditis. This paper will not include a consideration of chronic rheumatic endocarditis.

ACUTE BACTERIAL ENDOCARDITIS

This condition was known to older writers as endocarditis lenta, and as malignant, ulcerative, septic, or septic bacterial endocarditis. Clinically, acute bacterial endocarditis is not as important from a cardiac standpoint as the other two main groups.

Staphylococci and streptococci, *Neisseria gonorrhea* and *Diplococcus pneumoniæ* are the organisms most frequently responsible for the disease. Cases have been reported that were due to *Eberthella typhi* (typhoid bacilli), *Mycobacterium tuberculosis, Bacillus anthracis, Corynebacterium diphtheriæ, Neisseria intracellularis* (meningococci), and *Escherichia coli* (colon bacilli).

There is a greater variance of opinion concerning the incidence, symptoms and mortality of gonorrheal endocarditis than concerning the other types of acute bacterial endocarditis. Gonorrhea is not a common cause of heart disease, as is illustrated by the fact that Cabot failed to find a single case with this etiology in 1906 postmortem examinations in cases of cardiac disease. It is often stated that gonorrheal endocarditis is less acute and not as malignant as are the other types of acute bacterial endocarditis, but in the proved cases it would appear that gonorrheal endocarditis is about as fatal as are the other forms of acute bacterial endocarditis.[10] Gonorrheal endocarditis is a direct result of gonorrheal septicemia, just as the other types of acute bacterial endocarditis are results of general septicemia or bacteriemia. Acute bacterial endocarditis, compared to the other types of endocarditis, is relatively rare.

Vegetations are practically always present in acute bacterial endocarditis, and usually there is loss of substance of the valves, in varying degrees, that frequently leads to perforation of a leaflet. The deeper structures commonly share in the process. The mitral valve is the one that is most commonly involved. Involvement of the aortic valve occurs next in frequency, and invasion of both aortic and mitral valves occurs with less frequency. The tricuspid valve alone is rarely affected.[9,11]

It is difficult to reconstruct a satisfactory clinical picture of acute bacterial endocarditis. Previously injured valves are more likely to be involved than normal valves. The objective cardiac evidence may be that of healed rheumatic endocarditis. In the majority of cases the cardiac symptoms are only a part of the picture of generalized infection, and evidence that the heart is involved often is masked by the patient's critical general condition. Embolism is a frequent complication, and this often is the first positive proof of the cardiac involvement. The usual clinical picture in this group of cases is that of severe septicemia or bacteriemia. As a rule these cases run a course varying in length from a few days to a few weeks, and are practically always fatal.

As has been stated in the foregoing, subacute bacterial endocarditis, and acute and recurring rheumatic endocarditis, are the types that are most difficult to differentiate and they are the cases that merit special consideration.

---

*From the Section on Cardiology, The Mayo Clinic, Rochester, Minnesota. Submitted for publication January 21, 1931.

Table 1

DIFFERENTIAL DIAGNOSIS OF (ACUTE AND RECURRING) RHEUMATIC ENDOCARDITIS AND SUBACUTE BACTERIAL ENDOCARDITIS

	Subacute bacterial endocarditis	Rheumatic endocarditis (acute and recurring)
Etiology	*Streptococcus mitior* (viridans)	Rheumatic fever, chorea, tonsillitis (streptococci)
Incidence	0.5 to 1 per cent of all cardiac diseases	18 to 20 per cent of cardiac diseases (including chronic)
Sex	About equal numbers of males and females	More common in females
Age	Occurs in older group 5-10 years	Begins usually with patients less than 30 years of age
Leukopenia	May occur	Rare
Leukocytosis	Rare, unless sepsis present	About 50 per cent of cases
Anemia	Slight in the early stage; later, usually marked and progressive	Rare and slight if present
Petechiæ	Common	Absent, or rare
Nephritis	About 50 per cent of cases; Higher in late stages Albumin; erythrocytes; high value for blood urea is rare	Absent
Osler's nodes	Common	Rare
Janeway's nodes	Occurs, but not common	Absent
Infarction	Common	Absent or very rare
Purpura	Rare	Absent
Severe, diffuse, cutaneous lesions	Very rare	Absent
Temperature	Usually continuously above normal and often septic in type	Usually increased and intermittent
Spleen	Usually enlarged	Normal
Physical signs	Usually those of chronic valvular heart disease	In recurring type, those of chronic valvular heart disease
Auricular fibrillation	Rare	Common
Pericarditis	Rare	More common than other group
Course	Fatal, usually in two years	Tendency to recover with valvular defects
Involvement of joints	Absent or rare	Common
Acute myocarditis	About 23 per cent of cases that come to necropsy	88 to 100 per cent of cases that come to necropsy

ACUTE AND RECURRING RHEUMATIC ENDOCARDITIS

The etiology of rheumatic endocarditis is rheumatic fever. It should be emphasized that rheumatic fever is an infectious disease that is almost as widespread and extensive as syphilis and tuberculosis. It is fairly well agreed by the best authorities that rheumatic fever is due to infection with streptococci. In eliciting a history relative to the heart, it is a universal practice to ascertain whether or not the patient has ever had rheumatic fever, chorea, tonsillitis, scarlet fever, or "growing pains." In the majority of cases a definite history of rheumatic fever is obtainable. In other cases a positive history of chorea, tonsillitis, scarlet fever, and growing pains will be obtained. Growing pains are not always significant, but as Swift well pointed out, their occurrence in children, with infection, should be viewed with concern. It is becoming more evident, and in time there may be little doubt, that chorea, tonsillitis, and in certain instances, growing pains, are different clinical phenomena of that diffuse and extensive disease known as rheumatic fever. I do not believe that the common and acute follicular tonsillitis is often an etiologic factor in the production of endocarditis, but the tonsillitis that is part of the picture of rheumatic fever is a very important factor. Up to the present time these types of tonsillitis are not satisfactorily differentiated. Halsti, in his carefully controlled histologic studies, has shown that there are marked inflammatory foci in all types of diseased tonsils, but that in the tonsils of patients with rheumatic polyarthritis or heart disease there occur more intense mural changes in arteries of medium size than are found in tonsils from patients with other diseases. Rheumatic endocarditis is more common in females than males. The disease usually makes itself manifest before the age of twenty-two years. It is rare for this disease to have its onset after the age of thirty-two years.

Table 2

DISTRIBUTION OF LESIONS IN 109 CASES OF RHEUMATIC ENDOCARDITIS

	Acute	Chronic	Total	Per cent
Mitral valve	42	57	99	90.8
Aortic valve	20	43	63	57.7
Tricuspid valve	19	26	45	41.0
Pulmonic valve	3	1	4	3.3
Myocardium	46	28	74	67.8
Pericardium	7	34	41	37.5

The early pathologic changes that occur are infiltration, induration, and edema of the cusps, and these changes may be restricted to a small area or they may be diffuse.[12]

The vegetations in the rheumatic group of endocarditis are small, rather firm, fairly smooth, globular or warty in appearance, and occur more often at a point of contact and on the free margins of the valves. They may be attached by pedicles of varying lengths.[11] The left side of the heart is more often involved than the right. Van Glahn, in a series of 109 cases, found the distribution of the lesions as given in Table 2.

The early vegetations are composed of bacteria, blood platelets, leukocytes and fibrin in varying degrees. The Aschoff body is characteristic of this lesion. It is described as a minute nodule, composed of wandering cells concentrically arranged, scattered throughout the heart wall and especially in relation with small arteries.[9] The vegetations are later replaced by connective tissue. The affected valves may be restored practically to a normal condition, or the process may extend to ulceration. The vegetations in this type of endocarditis rarely form emboli, and some writers go so far as to say they never do. In most instances, the valvulitis extends on to varying degrees of scarring and deformity.

Many theories are advanced concerning just how and when the initial lesion occurs. The three most probable sites are given as (1) the covering of the endocardium, (2) tissue in and about the blood vessels of the valves, and (3) the valve rings, from foci situated in them.[12]

The clinical course and physical features of acute and recurring rheumatic endocarditis often are not very definite or characteristic, and for this reason they are frequently overlooked.

In a case of rheumatic fever, whether it is the first siege or whether it is a recurring attack, if the patient becomes more toxic, if pulse and temperature rise in the presence of increasing pallor and without sufficient cause (that is, if the involved parts do not become aggravated) one should be suspicious of involvement of the endocardium. The objective cardiac signs that may appear early in the disease are slight roughening of the first sound at the apex, heart tones that are rather weak and lack definition, and often gallop rhythm. The roughening of the first sound may develop into a definite murmur.

Leukocytosis is present in about 40 to 50 per cent of the cases. As a rule, leukocytosis does not aid materially in distinguishing acute and recurring rheumatic endocarditis from subacute bacterial endocarditis. It is more common in acute and recurring rheumatic endocarditis. Leukopenia is extremely rare. Anemia, in contrast to leukopenia and leukocytosis, is a very important factor in the differential diagnosis of subacute bacterial and acute and recurring rheumatic endocarditis. Mild secondary anemia is not uncommon in acute and recurring rheumatic endocarditis, but is rarely as severe and progressive as it is in the subacute bacterial type. The same may be said concerning leukopenia as has been said concerning leukocytosis; that is, it is not a very important differential feature. Joints are involved in about 90 per cent of the cases at some stage of the disease. Nephritis in acute and recurring rheumatic endocarditis is extremely rare, whereas it is a common complication in subacute bacterial endocarditis.

SUBACUTE BACTERIAL ENDOCARDITIS

The term "subacute" is not entirely satisfactory, but up to the present it more accurately describes the condition than any other term that has been presented. The term "acute" cannot be used because some of the patients live about two years. The term "chronic" is inapplicable because some of the patients may die within a month or so, and too, the term chronic well describes the scarred and deformed valve of rheumatic endocarditis.

Subacute bacterial endocarditis is practically always the result of *Streptococcus mitior (Streptococcus viridans).* Libman found *Hemophilus influenzæ* (influenza bacillus) present in a higher percentage of his cases than has been found at The Mayo Clinic, where *Hemophilus influenzæ* has been found in only one case, and this case belonged to the acute rather than to the subacute bacterial group.

Subacute bacterial endocarditis practically always involves valves that have been previously injured, and the injury, in the majority of cases, has been due to previous rheumatic endocarditis. Occasionally the injury may be the result of a congenital defect, arteriosclerosis, or syphilis. The distribution of valvular lesions, that is, the order of frequency of valvular involvement, is essentially the same in the other forms of endocarditis.[4] Active pericarditis is very rare in subacute bacterial endocarditis. It occurs much more commonly in the rheumatic group of cases. The gross vegetations in this group are larger and more irregular than in the rheumatic group; they are soft, villus-like, and are not as smooth as the rheumatic vegetations. It is common to find several chordæ tendinæ severed.[9, 11]

The urine in this group of cases usually contains some erythrocytes, albumin, and occasionally casts, but as a rule renal function remains good up to the late or terminal stage.

The types of nephritis in subacute bacterial endocarditis are more interesting from a pathologic than from a clinical point of view. One of three types of nephritis may be associated with subacute bacterial endocarditis: (1) embolic nephritis, in which the kidney contains multiple small abscesses but has relatively good renal function; (2) diffuse nephritis that is due to gross infarction, and (3) diffuse subacute glomerulonephritis. In a small percentage of cases, all the glomeruli will be involved, and microscopically the condition looks like that seen in true diffuse glomerular nephritis.

If the concentration of urea in the blood rises to 250 or 300 mg. in each 100 c.c. before death, usually one can predict, with a fair degree of accuracy, that diffuse subacute glomerulonephritis will be found at necropsy.[2]

Baehr described the salient features of the glomerular lesions as "involvement of one or more loops of a variable number of glomeruli and an absence of any visible disease in the uninvolved portions of the affected glomeruli."

These patients usually look sick, and as a rule they are. Their temperature usually is continuously above normal, and it is often septic in type. There are afebrile stages that have been described. The patients may have pain that involves the muscles and joints. As a rule, however, the pain is not severe, and the regions of involvement are not so extensive as in the rheumatic group of cases. The objective cardiac findings are usually those of preëxisting valvular disease.

Petechiæ are common. They occur on skin and mucous membranes. Most often they occur on the anterior surfaces of arms, hands, and body. The conjunctiva of the lower lids is a very common site of petechiæ, and their occurrence in this region is almost pathognomonic of the disease. Petechiæ on the conjunctiva usually occur singly, and have a creamy-white center. The petechiæ occasionally occur in groups or showers. They may be present for a few days and then disappear, to be followed by another shower. They may be numerous or there may be just a few in scattered areas.

Janeway's lesions are not common, but do occur. They are described as small, slightly nodular hemorrhagic lesions, not tender, and occurring principally on the palms of the hands and the soles of the feet.[14]

Rheumatic nodules, originally described by Meynet, are also known as Osler's nodes. Osler described them as small, firm, hard subcutaneous nodules, that vary in size from that of a small shot to that of a large pea, and which occur most frequently on fingers, hands and wrists. They may occur on the elbows, feet, knees and back. As a rule, they are distinctly tender and painful. They may last from a few days to a few weeks, and even months. They are made up of round and spindle-shaped cells.

Purpura may occur, but it is rare. A few cases in which there were severe, diffuse, erythematous lesions have been described.[5] Judging from the duration of the clinical course of the cases reported in which these erythematous lesions have occurred, it appears that they should be classified with the cases of acute bacterial rather than with the cases of subacute bacterial endocarditis. Infarction of the spleen, kidneys, and brain is common. Anemia is present and usually is marked and progressive. Leukocytosis is very rare unless sepsis is present. Leukopenia occasionally occurs. Active pericarditis is rare in subacute bacterial endocarditis, but scarring due to preëxisting pericarditis is fairly common. Auricular fibrillation is very rare in subacute bacterial endocarditis,[8] but common in the recurring rheumatic form. Splenomegaly is present in the majority of cases. It occurred in only 46 per cent of Clawson and Bell's cases. Fox, in his pathologic studies, found infarct to be the most important gross lesion in the spleen, and perisplenitis was present in practically every case. He found further that the enlargement of the spleen was due mainly to the infarcts, generally hyperplasia, and increase in the amount of blood.

Positive blood culture is present in about 85 to 90 per cent of the cases, and in the atypical cases this is probably the most important factor in making a diagnosis.

NAME OF NARCOTICS DIVISION CHANGED TO DIVISION OF MENTAL HYGIENE

In a recent report, Surgeon General H. S. Cumming of the Public Health Service indicates that the year ended June 30, 1930, has been characterized by additional legislation seeking to coördinate and crystallize the functions of the Narcotics Division, now designated by law as Division of Mental Hygiene.

At the close of the year, the functions of the Division of Mental Hygiene, in the office of the Surgeon General, included the administration of the two recently authorized United States narcotic farms; studies and investigations of the nature of drug addiction and the best methods of treatment and rehabilitation of persons addicted to the use of habit-forming drugs; the dissemination of information on methods of treatment and research in this particular field; coöperation with State and local jurisdictions with a view to their providing facilities for the care and treatment of narcotic addicts; the supervising and furnishing of medical and psychiatric service in Federal penal and correctional institutions; studies and investigations of the abusive use of narcotic drugs and the quantities of such drugs necessary to supply the normal and emergency medicinal and scientific requirements of the United States; and, lastly, studies and investigations of the causes, prevalence, and means for the prevention and treatment of mental and nervous diseases.

The site for the first United States Narcotic Farm has been selected at Lexington, Kentucky, and plans are under way for the development of the necessary buildings thereon. Medical officers have been assigned to the medical and psychiatric clinics established at the several penal and correctional institutions.

AN UNEXPLOITED THERAPEUTIC OPPORTUNITY IN PERIODIC HEALTH EXAMINATIONS OF YOUNG ADULTS*

Norman Johnson, M.D.
Minneapolis

THE following paper presents certain ideas which have crystallized out from time to time in meditations over a type of problem seen frequently by internists, the answer to which problem seems never to have been attacked in any organized way either in medical education or to any degree in the literature. The reason why we do not cope well with these problems in our education is chiefly because we are so ignorant,—ignorant of the factors involved and especially ignorant of how to cope effectually with such of the factors as we do partially understand. Then too, we are, as a branch of science, very prone to investigate, to show a studious interest in, and to teach, only subject matter which can be proved in a test-tube, reduced to a mathematical formula, or is otherwise susceptible of laboratory methods of examination. Such a tendency is unfortunate, but it is a line of least resistance and therefore one which will probably be continued. It falls down in clinical practice because the human being cannot be reduced to a mathematical formula or a test-tube reaction.

These are the clinical events which prompted my subject for this paper. In one period of ten days during the past year I had to advise four men that they abandon all business immediately for a period of time, varying from a few days to four months. One was a lawyer whose chief complaint was right upper quadrant colic for which pathology could not be demonstrated—a functional spasm perhaps. Another was the business physician for one of the largest lumber interests in the country,—the man on whom the business difficulties eventually were unloaded for settlement. He had reached a point where he would break into a profuse perspiration on trying to open a window, and he admitted that to put his head out of the window and scream would have afforded him considerable relief. The third man was one of a firm faced with insolvency. He came to me because he could not sleep except with sedatives, and then not more than four hours a night. He was losing weight, becoming very nervous and irritable, and during a few weeks time his blood pressure mounted twenty points to 160 systolic. He was able with guidance to close out his business without a break in compensation. A new business venture was successful for a time. During this period, he slept well without drugs, gained weight, lost his nervousness, and experienced a drop in blood pressure, but with the business depression last Spring, difficulties again developed and the whole syndrome, augmented by transient paling of finger tips, loss of appetite, despondency, and sweating, recurred. He could not talk about his business without tears. Thyroidism was suspected but could not be proved. He could not sleep even with drugs. During this period the blood pressure elevation reached 190/110. A vacation of four months was insisted upon. He closed out his business and when last heard from was markedly improved in every way except financially. The interesting corollary is that his brother—a business partner—went through the same experiences without having to consult a doctor. What is the difference in these two men? It is of course the difference in what we label "temperament"; it is the difference in equanimity or in mental serenity while under pressure. The one, through his thoughts, fears, blasted hopes, worries, disappointments, upsets the balance in his vegetative nervous system with resultant physical symptoms. The other went through the same experience and was still able to carry on at the time he most needed to carry on.

These are the simpler types of cases which seem clean cut. To carry the concept of symptom-etiology further into pseudo-clinical entities is a procedure fraught with danger and difficulty. The possibility of the existence of true physical disease in spite of inability to prove its actuality will always remain to plague the diagnostician with doubt. To illustrate: the head of a large mercantile establishment has had four attacks of acute right lower quadrant pain closely resembling appendicitis. All of these attacks have disappeared after twenty-four to thirty-six hours of rest in bed. I have not yet felt fully justified in advising operation in any attack, chiefly because I know his temperament rather well and suspect he may be producing these attacks himself. In support of this belief is an X-ray diagnosis of spastic colon. I also see him occasionally for attacks of extrasystoles which he may well bring on himself through a state of high nervous tension. As a parallel case, I have that of a music teacher who taught fifty-four music pupils a week, became engaged, married—with all the social obligations attendant thereto—did her own housework, and, following a period of great excitement one evening, developed acute epigastric pain, vomiting and some diarrhea. After thirty-six hours, the pain localized in the right lower quadrant, the leukocytes reached 13,000 (note vomiting and diarrhea) and a surgical consultant thought he could palpate an appendiceal abscess. Operation revealed a normal appendix and no explanation for the pain or vomiting was forthcoming. However, right lower quadrant pain severe enough to require day and night special nurses continued for three weeks after operation.

---

*Read before the Minnesota Society of Internal Medicine, Rochester, November 10, 1930.

Now none of these patients, except the bride, was neurotic or hysterical. If any practice contributes four cases in ten days of any one condition sufficiently severe to disable a patient, that condition must be an important factor and worthy of reflection. If there are cases producing disability, there are many more of lesser degree. In other words, organic dysfunctions not due to disease, hysteria, or neurosis must be fairly common in life, and the internist will be the logical one to see many of these cases. I believe that a large percentage of our working population are potentially cripples or may become so under a given situation or succession of adverse circumstances. I have asked myself time and again,—why do we have these physical manifestations of dysfunction? What can we do to prevent them?

The answer to the first question is obvious. So far as our motor and secretory functions are concerned, we are all controlled by a vegetative nervous system. Much has been said and written, but little is actually known, about this control. We know that, with a few exceptions such as bladder and rectum, these functions are beyond control of the will, but they are very much influenced by emotional stimuli. We have heard of the vasotonic and sympathetico-tonic types of individuals, but these labels connote an inherent or inborn imbalance of the vegetative nervous system and comprise only a small group of the total population, whereas I believe that a great many of us actually develop a very hair-trigger mechanism to all autonomic reactions.

One recent piece of physiological research may have bearing as evidence in incriminating the autonomic nervous system as a source of disability. In working on conditioned reflexes in dogs, attempt was made to quantitate the response to stimuli. Interpretation of results seemed to show that where the stimulus was pleasurable, repetition over longer periods seemed to cause progressively diminishing response (saliva containing less solids and of lower specific gravity) whereas if repetition of unpleasant stimuli was tried, intensification of the reflex action seemed to increase with the same strength of stimulus. If true, this may be exceedingly important to the human undergoing recurrent unpleasant experiences.

There are many disease entities of unknown etiology which might with some justification be assigned as to origin to a disturbance, prolonged over many years' time, in the delicate adjustments affecting motility, secretion, or irritability of organic structures. Such a group might include the primary disorders in vascular control such as Raynaud's coronary disease, hypertension, or angio-neurotic edema. It could also be extended to include diseases due to sudden change in the vascular flow, such as certain headaches, epilepsy, periodic amblyopia, abdominal migraine, acrocyanosis, hay fever, and many gastro-intestinal complaints. In the same related group might also be placed asthma, exophthalmic goiter, Hirschsprung's disease, spastic constipation, certain diarrheas, and even ulcer and diabetes. If entities such as these may be related to imbalance in vegetative control, then there must be also a large group of symptomatic difficulties with a similar basis in etiology that can attack the human, even to the degree of complete disability. This I believe to be the cause of at least some of the disabilities in the cases mentioned,—which brings me to the second query—What can be done about it?

To attempt to change the habits of thought, or the state of mind or of temperament, in a man or woman of forty-five is not easy. It may not even be possible. I would rather attempt to change his religious or political prejudices. In each of the cases mentioned, the end-result was satisfactory and yet the treatment was only palliative—which is not the highest goal of therapeutic achievement. What *can* one do? He may give advice to stop worrying, which doesn't stop the worrying. He may comb the body for foci on which to put the onus of symptoms. He may give sedatives, or medication designed to alleviate the presenting symptoms, just as he may give insulin to the diabetic, which will not often cure the diabetes though symptoms are relieved. Or, better yet, he may attempt to strike prophylactically at the source.

This is now the fifth year that I have had the pleasant experience of making periodic health examinations on students at the University. Except for some entering freshmen in the past two years, these are graduate students. They fill out an extensive questionnaire, have performed a very complete set of routine laboratory tests and come to the physician for a thorough physical examination and a survey. The defects in habit or physical equipment, and all symptoms complained of, are discussed and appropriate advice given. One hour for each student is the allotment with the physician. Some require less time; some a great deal more. It is in talking with and studying these students that many illuminating and thought-provoking problems occur. Together with a great many other things, I am sure I can find amongst this selected group of approximately healthy beings, the prototypes—the anlage if you will—of the type of person mentioned before. These defects which, under given conditions, may produce disability, or unhappiness, are not necessarily a heritage. More frequently, the student himself develops the mental state which makes him so vulnerable to the buffets of a competitive and sometimes cruel life ten or twenty years later. It is my belief that mental reaction habits are formed during school years, along with a great many other reactions to which a person by constant and daily repetition becomes habituated. For instance, most students have early formed the habit of washing their faces in the morning—a simple thing—and yet it has become so much a part of their lives that to remove this daily ritual would make them decidedly uncomfortable—for a time at least. Likewise, they are forming or have already formed habits of study, of eating, of sleeping, of defecation, of exercise, all of which they will continue as they have begun unless something interrupts the habit-continuity. If this is true, it should be profitable to enlist the intelligence of the youth himself toward making some definite attempt to shape up a group of habits which will not leave him vulnerable later. Better steer a course than float blindly with the stream. From the time he leaves the pediatrician, and discards his blind allegiance to parental advice, until he finds himself in trouble, there is no one making any organized attempt to train the individual toward the ability to remain serene under adversity or pressure. This is a period of twenty years or more, and when it is over, whatever has been put together by haphazard methods is so thoroughly "gelled" that it cannot be undone if it is bad. All of which is one reason why so many excellently trained and talented men and women are prevented by their own temperamental limitations from accomplishing anything "big." They "crack up" under pressure because they do not know how to use their capacities to fullest advantage.

There is no science to aid the physician who attempts to guide the youth in developing what I have called mental serenity. Perhaps the Christian Scientists do it passingly well. Osler, in a little essay delivered to the Yale students called "A Way of Life," has told how he worked out his own salvation to permit him to accomplish a very busy life without physical disaster. He also has written his famous essay on equanimity. These furnish the germ of the idea which I am trying to present, *i.e.*, of the necessity for making an effort to develop, along with other developments, the ability to handle oneself. If a man spent one quarter of the time and effort which he uses to make his business efficient toward making himself a smoothly running machine, there would be fewer casualties and more genius available.

The earlier a beginning can be made in such training, the easier obtained the results. I speak from an experience only with students, which is a select group having distinct and specific problems not occurring in the world at large. Yet the general reactions of nervous excitability, of too great intensity, over-conscientiousness, and self-consciousness, are present everywhere, and the stimuli which serve to aggravate them may be found in one form on the campus and in another in the shop. Only, I believe, the more highly organized the intelligence, the greater the susceptibility to overstimulation. Hence the college campus should furnish more material per capita than the industrial plant.

The specific points to be emphasized in the hope of creating an intelligent awakening in the student toward what he is doing may be only mentioned in passing. Each person presents a different combination, and each needs an individualized approach. One of the numerically greatest of the habits which I ask the student to consider is that of a highly developed sense of duty coupled with a false standard of values—the conscientious student. He, or usually she, received high marks in high school where effort and conscientiousness receive their reward in grades. In the University, this student is just another Ford being put through the factory, and grades are issued impersonally on the basis of an examination which may have created such a psychic response in this particular student at the time it was given as to result in a poor grade. Then the next examination is worse and I have repeatedly seen students of eighteen with constant pulse rates over 100, blood pressure near 160 systolic, even at rest, who admit to being paralyzed with fear at each successive examination. The fault here is the universal emphasis on the importance of the grade as an index of the efficacy of time spent in college. No one yet has been eminently successful in life because of high marks in college, but many have failed in life because, in striving over four to twelve years for high grades, they have only learned the ability to get out of control—vegetatively speaking. So I try to teach them, if conscientious, that it is important to know when to be and when not to be conscientious.

Then there are the high degrees of self-consciousness, always coupled with a high degree of instability in the vegetative nervous system. Four years of improper handling in college may clinch for this student a reaction habit which will end in his downfall when put under pressure. For instance, one senior dentist told me that, as a freshman seven years before, he was so self-conscious that he would go many blocks beyond his car-stop before he could bring himself to push the button. Imagine this man thrown out into the business world! How vulnerable he would be to physical catastrophe! This type I usually send to the mental hygienist. They are very difficult.

Again there is the boy who must, outside of school, work forty hours a week in order to support himself in graduate school. The mere situation of being constantly behind day after day, of being constantly pushed for time between his job, his classroom, his studies, meals and sleep—always at the expense of outdoor relaxation—creates in a few months' time a state of sustained intensity. They are always tense. Blood pressures and pulse rates are frequently elevated. In life afterward they will be the high-pressure big-business men and perhaps will die of coronary disease at fifty. This type needs to be taught the value of artificial relaxation, of utilizing short snatches of time for turning off the switch, and that is a very difficult thing to learn—how to turn off the switch. Especially they must learn Osler's dictum of living in water-tight and air-tight compartments of twenty-four hours each, and of not projecting themselves into the mass of work waiting to be done until it is time to be there in person. Though the individual may need to work fast, he must also learn how to segregate physical speed and to eliminate mental hurry. To use a railroad analogy, living in the block system is one thing a great many of us could learn with profit.

There is a question to be checked: "Do you worry?" Here the examiner must be careful. It is frequently answered in the affirmative but usually the worry is only a minor feature, perhaps about whether or not the money will last out the term. Occasionally the affirmation was furtive and you catch a suspicious circumstance in the way your questions are answered. It is not at all remarkable to uncover here a problem of considerable magnitude. But also, questioning may uncover that vicious fault in any age—the chronic worrier. Perhaps some are born with the attitude; perhaps it is developed from parental examples; I am sure it can be learned and amplified in college life. I have tried to formulate a succinct expression for use to instruct this type. I point out the block system type of life, but above all I emphasize doing a thing to the best of one's ability and then facing the consequences, whatever they may be. It is fear of consequences which seems to me to keep this type in a state of constant mental agitation.

These few examples will suffice to show what seems to me to be a therapeutic field of considerable importance. It borders on the psychiatrist's province but he is as unqualified from the physical-clinical side as an internist is on the technical side of psychiatry. Besides, we have very few psychiatrists with us. The essential therapeutic duty of the internist is, after all, that of a teacher. We have only a dozen or so specific cures. We have to instruct the cardiac patient on how to live best with whatever type of heart trouble he has. We teach the diabetic how to manage his disease. Why is it not as justifiable for us to attempt to teach the youth how to avoid functional disabilities as it is to educate them on how to avoid tuberculosis or venereal disease. Only the program is very much more difficult to put over for the reason that it cannot be learned in one year of effort any more than one can play symphonies after one year of piano lessons. That is why the college course is so admirably suited to this therapeutic attack. The student is devoting four years to education, usually without other major responsibilities. He is above average intelligence, can grasp its significance, and is receptive. He is still in his formative years and the physician can take inventory with him annually, or oftener if desired, giving encouragement and advice. I make a plea merely that we shall be somewhat aggressive in seizing any opportunity given us to add to his educational armament some instruction in the Art of Living and incidentally in stopping at its source one agency of disease.

338 LaSalle Building.

THE STROOPAL FRAUD

For many years a nostrum known as Stroopal has been sold on both sides of the Atlantic as a cure for cancer. The product apparently originated in Germany. For some years it was exploited from London and was exposed by London *Truth* nearly twenty years ago. According to Gehe's Codex, Stroopal is composed of the powdered leaves of *Teucrium Scordium,* otherwise known as water germander or wood garlic. For at least seventeen years, Stroopal has been exploited in a small way from Chicago. Recently, Stroopal seems to have been advertised under the name of the Stroopal Company, 2101 Belmont Ave., Chicago. On August 13, the postal authorities issued a fraud order against the Stroopal Company and notified the Chicago postmaster to return all letters addressed to the Stroopal Company to the original senders. (Jour. A. M. A., October 4, 1930, p. 1037.)

THE HORMONE OF THE ADRENAL CORTEX

The Swingle-Pfiffner cortical hormone "extract" has been tested in cases of Addison's disease at the Mayo Clinic. Hartman, Brownell and Hartman also have been able to prepare an extract of the adrenal cortex that will prolong the lives of adrenalectomized animals indefinitely. They also have revived a patient with Addison's disease having a systolic blood pressure of 50 mm. and a pulse of 120 a minute by the use of their preparation of the hormone, for which they propose the name Cortin. "Cortin" administered by mouth appears to give little or no benefit. It is best administered subcutaneously except in circulatory failure in which absorption is greatly reduced; then intravenous injection is employed. One may soon confidently expect the relief of the dire Addison's disease by the cortical hormone. (Jour. A. M. A., January 24, 1931, p. 273.)

SPINAL ANESTHESIA*

Ralph M. Tovell, M.D.
Rochester, Minnesota

SPINAL anesthesia, or subarachnoid block, was first advocated by Corning in 1885. Although Corning's report was based on a false premise his suggestions led to discovery of the truth. In the course of experimental work on root pain, while he was doing a paravertebral injection with cocaine, he accidentally produced spinal anesthesia. He said that it was not essential to deposit the solution within the dura, but that close proximity to the spinal cord or its coverings was sufficient. He based his conclusion on the supposition that the solution would be carried into the spinal canal by the blood vessels. It is now known that this is an erroneous view. Since then the technic has varied, and this method of anesthesia has had brief periods of popularity. With the discovery of procaine, an added factor of safety was found, but not until the use of ephedrine became general did spinal anesthesia gain real favor. During the stages of transition the physiologic changes due to blocking of the spinal rami have become more evident and a rather precise technic has been developed.

SIGNIFICANT CONSIDERATIONS

There are several considerations of significance in the administration of a spinal anesthetic agent: (1) Choice of patients, (2) preliminary medication, (3) dose, (4) site of injection, (5) amount of spinal fluid to be withdrawn in which the crystals of procaine will be dissolved, and (6) rate of injection. I shall consider these points in the order given.

Choice of patients.—Extreme differences of opinion regarding the safety of spinal anesthesia have been expressed by various authorities. At The Mayo Clinic, the use of spinal anesthesia has been limited to operations below the diaphragm. This method is indicated particularly for patients suffering from emphysema, advanced asthma, chronic bronchitis, and other respiratory conditions, for whom a general anesthetic given by inhalation is contraindicated. Spinal anesthesia may be warranted for patients suffering from intestinal obstruction, extravasation of urine, or senile or diabetic gangrene, in whom the disturbance occasioned by a general anesthetic often diminishes chances for recovery. It is also useful for catheterization of the ureters in a patient in whom a highly sensitive tuberculous or cord bladder is present. Because a few centigrams of the drug have so little effect on the general cellular metabolism, spinal anesthesia is indicated in cases in which the kidneys are not functioning properly. Throughout this country the popular tendency is toward the use of spinal anesthesia for all operations below the diaphragm except in cases in which certain conditions are present, as follows:

1. The procedure is contraindicated in the presence of involvement of the central nervous system by a tumor of the spinal cord, syphilis, epilepsy, intracranial hemorrhage or intraspinal hemorrhage. Cases in which the spinal fluid is turbid, although no other pathologic change is found, should be included in this group.[3]

2. Local pathologic processes at the intended site of injection preclude its use.

3. Patients in whom the blood pressure is extremely high generally experience marked reactions following induction of spinal anesthesia, and in such subjects the dose used must be conservative. Patients with hypotension are often poor operative risks, especially if cyanosis and decompensation are present. Operations above the lower part of the abdomen should not be performed under spinal anesthesia if the systolic blood pressure is below 100 mm. of mercury unless a general anesthetic is absolutely contraindicated.

4. Patients in a state of severe traumatic shock are poor risks for any form of anesthesia. If the shock is not of hemorrhagic origin spinal anesthesia may be used, and is satisfactory when crushing injuries involving the lower extremities are to be treated. In some in-

---

*From the Section on Anesthesia, The Mayo Clinic, Rochester, Minnesota.

stances, due to the breaking of the reflex arc, shock may be partially controlled by the anesthesia. I used the phrase "not of hemorrhagic origin" advisedly because, in a recent article, Burch, Harrison and Blalock reported that hemorrhage in spinal anesthesia is much more likely to cause shock than the same blood loss under ether. Under ether anesthesia, withdrawal of blood equal to 3 or 4 per cent of body weight produced marked decline in cardiac output and blood pressure, but the animals were not in grave danger of immediate death. Under spinal anesthesia death was produced by removing an amount of blood which varied from 0.5 to 1.6 per cent of the body weight. It would seem, therefore, that spinal anesthesia is contraindicated if patients have lost a great deal of blood or if severe loss of blood during the operation is anticipated.

5. Spinal anesthesia should not be used for patients with septicemia or pyemia. The protective barrier between the infected blood and the nerve centers would be eliminated by the puncture.

6. For patients with diminished breathing capacity due to pleural effusions or intrathoracic tumors, combined with lower concentration of hemoglobin, spinal anesthesia is definitely contraindicated.

Preliminary medication.—Several drugs in different combinations and doses have been tried to control the patient's natural dread of an operation, and at the same time to insure his cooperation. The evening previous to operation sodium ethyl methyl butyl barbiturate (nembutal) 100 to 200 mg. (1½ to 3 grains) are given by mouth. One hour before operation it is of benefit to repeat the dose of the barbiturate and to administer morphine sulphate in a dose of 10 to 16 mg. (1/6 to ¼ grain) hypodermically. Instead of the barbiturate and morphine on the morning of operation, 10 mg. (1/6 grain) of morphine sulphate with 0.3 mg. (1/200 grain) of scopolamine hydrobromide may be given one and a half hours before operation and the scopolamine may be repeated one hour later, if necessary. In my experience, the combination of morphine and sodium ethyl methyl butyl barbiturate has been preferred. Unless it is intended that the spinal be combined with a general anesthetic, atropine is probably best omitted, because atropine has a characteristic action of paralyzing the myoneural juncture of all nerves which supply unstriated muscle. The line for vagal innervation is thus broken, and contraction of the intestines is rendered difficult even after the inhibitory sympathetic innervation is paralyzed following subarachnoid block. Therefore when contraction of the intestines is desired administration of atropine defeats one's purpose.

Dose.—As a routine, the history and physical condition are reviewed to discover possible contraindication to spinal block. On arrival in the operating room, the patient's blood pressure, age, weight and height are ascertained. An estimate of the patient's resistance is made and the dose of procaine is decided on, taking these factors into consideration, together with the site and the possible duration of the operation. In my opinion, from 1 to 1.5 mg. (1/64 to 1/40 grain) for each pound (0.55 kg.) of body weight is the best guide in the calculation of the dose of procaine, with 300 mg. (5 grains) as the maximal amount for any operation. The smaller doses should be given to old and debilitated patients, who are affected by hypotension and cardiac disease, recent extreme loss of weight, or decreased respiratory surface and lowered concentration of hemoglobin, with the attendant decrease in the power of the blood to carry oxygen. For operations on the extremities, perineum, or urinary bladder, I have found that a dose of 80 to 120 mg. (1 1/5 to 2 grains) of procaine is ample. For operations on the lower part of the abdomen 120 to 150 mg. (2 to 2 2-5 grains) is required, whereas for operations on the upper part of the abdomen, the gallbladder and the stomach, 150 to 300 mg. (2 2-5 to 5 grains) may be given.

If the blood pressure is normal, a hypodermic injection of 50 mg. (¾ grain) of ephedrine should be given five to ten minutes before introduction of the anesthetic agent. If the blood pressure is 160 mm. of mercury or higher, it may be desirable to delay the injection of ephedrine until the lumbar puncture needle is in place. Thus, if the lumbar puncture cannot be completed, one is guarded against unduly raising the blood pressure. If the systolic pressure is less than 100 mm. of mercury, it is advisable to give 50 mg. (¾ grain) of ephedrine twenty minutes before the spinal anesthetic is introduced; unless there is some response to the ephedrine it is advisable to use only a small dose of procaine. If the systolic blood pressure is much lower than 100 mm. of mercury, it usually is not advisable to give a spinal anesthetic unless the fall of blood pressure is due to the derivative of barbituric acid used in preliminary medication. One should not be unduly alarmed by such a drop in blood pressure when estimating the dose of procaine.

Site of injection.—For operations on the lower part of the abdomen, puncture is made between the third and fourth lumbar vertebræ, and for operations on the upper part of the abdomen, injection is made between the second and third lumbar vertebræ. Recently, at the clinic, we have found that for operation on the gallbladder and stomach injection is better made between the first and second lumbar vertebræ; occasionally injection has been made between the twelfth thoracic and the first lumbar vertebræ with good results.

TABULATION

DOSAGE AND DILUTION OF PROCAINE IN SPINAL ANESTHESIA*

Operation	Site of injection between lumbar vertebræ	Dose of procaine, mg.	Amount of spinal fluid, c.c.
Amputation of leg	3 and 4	100 to 120	3
Prostatectomy	3 and 4	100 to 120	3.5
Herniotomy (inguinal)	3 and 4	120 to 150	3.5
Appendectomy	2 and 3	120 to 150	4
Colostomy	2 and 3	120 to 150	5
Hysterectomy	2 and 3	150 to 200	5
On gallbladder	1 and 2	150 to 200	5
On stomach	1 and 2	200 to 250	6

*Spinal needle, gauge: 20 to 22.
Rate of injection: 0.25 c.c. each second.

Amount of spinal fluid withdrawn.—For operations on the extremities and lower half of the abdomen, for example, for cystostomy, prostatectomy or herniotomy, anesthesia will be sufficiently high if the crystals of procaine are dissolved in 3 c.c. of spinal fluid; for operations on the colon, 4 to 5 c.c. is sufficient. For operations on the gallbladder and its ducts about 5 c.c. of fluid generally proves satisfactory, whereas operations on the stomach require 6 c.c. of spinal fluid. In operations on the pelvis, such as hysterectomy, when packing off is likely to cause a feeling of fullness and distress in breathing, anesthesia must be fairly high (must extend fairly well cephalad) and 5 c.c. of spinal fluid is required. The height of anesthesia varies directly with the dilution; the higher the anesthesia desired, the greater should be the dilution. The dosage of procaine affects directly the duration of anesthesia; the larger the dose, the longer is anesthesia maintained. Directions for various operations are given in the tabulation.

Rate and technic of injection.—The method of induction of spinal anesthesia is as follows: The patient is placed horizontally on his side on a cart or operating room table. The blood pressure is taken, and the back is cleansed with ether. An assistant draws up the patient's knees and brings the head downward to get maximal bowing of the vertebræ without producing discomfort. A wide area over the lumbar and upper part of the sacral region is sterilized with iodin, and a sterile towel is draped across the area, with its vertical edge at the intercristal line, crossing the vertebral column at the level of the spine of the fourth lumbar vertebra. The interspace desired can be counted from this point. In obese patients, when the level of the intercristal line is obscure, the spine of the first lumbar vertebra can be found by the following maneuver and the site of injection determined. A point 7 cm. (or four fingers' breadth) from the median line is determined on each side at the lower border of the twelfth rib. The line joining these points crosses the vertebral column at the level of the spine of the first lumbar vertebra. As a final step, a perineal sheet is used to outline further the sterile field.

When the proper interspace has been determined, a cutaneous wheal is raised with a wheal needle; with a 50 mm. needle, 4 c.c. of 1 per cent solution of procaine, and 50 mg. of ephedrine are infiltrated along the course that the needle used for the puncture is to follow. The spinal needle, gauge 20 or 22, is inserted, and from 3 to 4 c.c. of spinal fluid is allowed to flow into the ampule containing the procaine. The stylet is then inserted to prevent further outflow of spinal fluid. The procaine is dissolved readily by repeated aspiration. The solution is then aspirated into the syringe from the ampule, the stylet is removed, the syringe is connected with the needle which has been inserted in the spinal canal, and the remainder of the estimated amount of fluid required is gently withdrawn. The solution is then injected, without pause, at a rate of 0.25 c.c. each second. As a check on the technic it is advisable immediately after injection is finished to aspirate 0.5 c.c. of spinal fluid. It is always a satisfaction to have spinal fluid aspirate freely and thus to know that the needle is still in the proper position.

The patient is then turned on his back and the head of the table may be lowered slightly until the operation is completed. The full Trendelenburg position may be employed if the surgeon desires. All changes of position should be made slowly and gently to prevent nausea, vomiting and respiratory embarrassment. Anesthesia develops in from four to ten minutes and is maintained for thirty to seventy minutes. For three hours after the operation the patient is kept lying flat on his back and the head is not elevated.

DESIRABLE AND UNDESIRABLE EFFECTS

Ideal spinal anesthesia insures perfect relaxation of the abdominal wall, contraction of the intestines, and consequent ease of exposure. Unfortunately, certain complications may occur both during and after operation. Failure to obtain anesthesia is disconcerting, but is due generally to faulty technic rather than to anatomic anomalies. If the anesthesia is not effective twenty minutes following the injection, a second injection may be made with comparative safety. Anesthesia which develops to within 3 to 7 cm. of the height desired is annoying but it may be supplemented with local infiltration of 0.5 per cent procaine, or nitrous oxide may be given.

During the first twenty minutes, there is usually a fall in the blood pressure of from 15 to 20 mm. A continued drop is of some concern. Three factors are involved.

The first factor is loss of vasomotor control. Normally there is a balance between the vasoconstrictors and the vasodilators.[6] If the vasoconstrictors or sympathetic fibers which arise from the first thoracic to the third lumbar vertebræ are paralyzed, the vasodilators or parasympathetic nerves, particularly the vagus nerves, become overactive and the blood vessels in the abdominal region dilate. The degree of drop in blood pressure is determined, to a large extent, by the height of the anesthesia and the number of sympathetic nerves involved. Fairly high anesthesia may be obtained without any alarming drop in blood pressure if the major portion of the procaine is deposited posterior to the ligamentum denticulatum and therefore more intimately in contact with the sensory than with the motor roots.[4] To accomplish this, and to prevent the solution escaping anteriorly through the denticulate margin of the ligament, injection of the procaine must be slow.

The second factor, slowing of the cardiac rate, depends on loss of balance between the vagus nerves, or inhibitory nerves, and the sympathetic or accelerator nerves. If the sympathetic fibers from the first to the fourth thoracic segments are anesthetized, the vagus nerves are left in control and produce slowing of the heart.

The third factor involved in the fall in blood pressure is paralysis of the thoracic and abdominal muscles. The pumping or aspirating action of the thorax is diminished; the heart receives a smaller amount of blood, and is therefore unable to supply the normal quantity to the brain. Cerebral anemia thus can develop. The Trendelenburg position is the essential treatment to offset this complication. Five minims of epinephrine administered subcutaneously may be given and the dose repeated once or twice. If the drop in blood pressure is late in the operation and is due to surgical shock, intravenous injection of physiologic solution of sodium chloride may be required.

With the fall in blood pressure there may be pallor, nausea, retching, and vomiting. Treatment of the fall in blood pressure ordinarily alleviates the nausea. The nausea often is psychic, depending on the mental impressions of an overactive mind. Sufficient preliminary medication and an entertaining anesthetist may eliminate this complication. The nausea may be reflex, caused by packing off too tightly or by manipulation of viscera of the upper part of the abdomen. The surgeon's coöperation is essential here. The treatment also includes deep breathing through the mouth, or intermittent inhalation of a mixture of 90 per cent oxygen and 10 per cent carbon dioxide. By this method, the pumping action of the thorax is improved, the blood pressure is raised, and the nausea is decreased. In a small percentage of cases, the retching may be so annoying to the surgeon that supplementary anesthesia with nitrous oxide or ethylene will be required.

Following the operation, headache is the most common complication. The patients usually complain of occipital pain appearing twenty-four hours after operation, which is worse when the head and shoulders are raised and is relieved when the head is lowered again. This pain is thought to be due to continued loss of spinal fluid through the lumbar puncture wound in those cases in which the arachnoid clings to the spinal needle as it is withdrawn and the arachnoid is herniated through the dura. This condition is rather intractable to any form of treatment and may linger for several days or weeks, but eventually it clears spontaneously. The incidence of headache is no greater following spinal anesthesia than following lumbar puncture for diagnosis when from 6 to 7 c.c. of spinal fluid has been withdrawn. It has been reported that a retention enema of 180 c.c. (6 ounces) of 50 per cent solution of magnesium sulphate gives relief. Surgical pituitrin, one ampule, or ephedrine, 50 mg. (¾ grain), given hypodermically produces improvement in some cases, but the essential factor in the ultimate result is time.

Meningitis is an ever-present possibility, but with aseptic technic such a complication can be avoided. Regions of numbness in the legs may persist for some time, but this numbness usually disappears without treatment. Ocular palsy, involving the lateral rectus muscles, is rare, but it may develop in the second week following operation. Squint develops and the patient complains of double vision. Fortunately, all such conditions reported have cleared without treatment. These complications are not common, but should always be thought of as possibilities. They have not been of sufficient significance to prevent spinal anesthesia increasing steadily in popularity.

In surgical procedures on the upper part of the abdomen particularly, nausea, and anesthesia of too short duration, are real problems. Variations in dose of procaine, in amount of spinal fluid used as a solvent, and in rate of injection, all have been given a trial. The incidence of nausea is highest in upper abdominal operations, but I still feel that to obtain satisfactory high anesthesia of sufficient duration, the dose of procaine should not be increased beyond the estimated limit of safety.

COMMENT

Properly induced spinal anesthesia, using any of the approved methods, produces complete freedom from pain in the operative field, absolute relaxation of muscles, contraction of the intestines, and relaxation of the anal sphincters which permits the escape of flatus and facilitates operative exposure. The small dose of drug is so placed to obtain the maximum of anesthesia with the least generalized toxicity. The fall in blood pressure occurs early in the operation, when the patient is best able to withstand it. The mucous membranes are not irritated as with ether, and postoperative vomiting is reduced to a minimum. The incidence of postoperative pulmonary complications is reduced. The method may be used for patients requiring emergency surgical procedures in whom slight infection is present in the upper part of the respiratory tract. Fluids can be administered by mouth earlier than following a general anesthetic.

Technically, the method of administration usually is fairly easy, but precision and dexterity must be acquired to obtain uniform results. The equipment necessary is standardized and easily procured.

Spinal anesthesia has its limitations. It is applicable in operations below the diaphragm and preferably below the umbilicus. The patient is awake and may fail to coöperate. Faulty technic in administration is more obvious than with a general anesthesia. With the use of procaine there is a definite limit to the duration of anesthesia and a general anesthetic may be required to complete the operation. The complications mentioned may occur during and following operation.

POTASSIUM THIOCYANATE IN HYPERTENSION

Thiocyanates resemble iodides in their therapeutic effect, but they do not affect the thyroid gland. As with iodides, the action of thiocyanates can not be satisfactorily explained. The reduction of blood pressure is dependent on the dose. The small dose of 0.1 Gm. (1½ grains) three times daily frequently fails to produce an appreciable reduction. The large dose, 0.3 Gm. (5 grains) three times a day, reduces blood pressure in a majority of cases but it is so liable to produce untoward results that such patients must be under careful supervision. The Council on Pharmacy and Chemistry has refused admission of potassium thiocyanate to New and Non-official Remedies because it considered the evidence for the drug's therapeutic value inconclusive and published a report giving the limitations of therapy with this drug. (Jour. A. M. A., February 21, 1931, p. 632.)

W. H. Y.

This product has been described by its exploiters, the Bartlett Nu Products Corporation, Azusa, Calif., as a "100 per cent pure, concentrated food beverage." G. M. Bartlett, President, Treasurer and General Manager of the corporation, claims to be the "discoverer" of the formula for W. H. Y., the ingredients of which are said to be extracts of raisins, figs, walnuts, peanuts, barley, wheat and celery. In 1928 a Notice of Judgment was issued against W. H. Y. because of the false and fraudulent claims contained on the trade package. However, Mr. Bartlett has apparently continued to make equally false and fraudulent claims in such advertising as does not go with the trade package. As W. H. Y. was sold through the United States mails, this brought Mr. Bartlett in conflict with the postal authorities, who have declared the exploitation of W. H. Y. fraudulent and debarred it from the mails. (Jour. A. M. A., March 21, 1931, p. 967.)

OBSERVATIONS ON SEROTHERAPY IN SCARLET FEVER*

Alexander Stewart, M.D.
Saint Paul

INCE the introduction of commercial scarlet fever antitoxin five years ago numerous ports on the results of this treatment have en published. Some of these reports have en very favorable as to the lowering of tem- rature, alleviation of symptoms and reduc- n in the percentage of complications and rtality. Cushing,[1] in 1926, reported a mor- ity rate of only 1.1 per cent, and a reduction complications by 25 per cent in those ated by antitoxin over the untreated cases e previous year. In a series of cases re- rted by Platow and Collins,[2] the rash dis- peared, the temperature returned to normal, d the symptoms were alleviated from one d one-half days to two days sooner than in e untreated controls. The Dicks,[3] in a group 100 cases, report nineteen complications in e untreated and four in the treated. Doo- tle[4] had 18 per cent complications in the ated, compared with 23.3 per cent in the ntrols.

Other reports comparing the treated with se untreated with specific sera have not own any appreciable beneficial results from e use of scarlet fever antitoxin. Toomey d Dolch[5] made an analysis of 1,658 scarlet er cases occurring in the Cleveland City spital and found the mortality rate very low the untreated cases.

I have been using antitoxin in scarlet fever tients, both on my service in the contagious spital and in private practice, ever since it s been available, and I thought it might be eresting to analyze the results of its use.

Of the cases occurring before the opening of e new contagious department at the Ancker spital, and in private practice, I have no mplete histories, so I have confined this dy to only those cases that occurred in my vice in the new Contagious Hospital in 28 and 1929.

The first serum used in the treatment of rlet fever was convalescent serum, and was first used by Weisbecker and Von Lyden in 1897 with doubtful results.[6] Later the method was made more effective by the work of Reiss and Jungman in 1912.[7] They collected blood from scarlet fever cases at the end of the third or fourth week, removing 100 to 200 c.c. from the veins of adult patients, and then obtained the serum by centrifuging. The pooled serum of at least three donors was placed in sterile ampules and kept in a cool place and was used for the toxic cases only.

In this country Zingher made use of whole convalescent blood, which he injected intramuscularly.[8]

My experience with convalescent serum has been limited to a few cases and has been confined exclusively to whole blood given intramuscularly. In some of the toxic cases I obtained a reduction in temperature and toxicity, but not nearly the marked improvement that we see following the use of the present scarlet fever serum.

For the last five years we have been using commercial antitoxin. At first the serum was so bulky and unconcentrated that we had difficulty in its administration, and had many severe serum reactions. Since then there has been a gradual refinement of the serum so that now the same units of antitoxin are furnished in one-fifth the quantity of serum, and we have much fewer and much less severe reactions.

Antitoxin has been used in the treatment, prophylaxis and diagnosis of scarlet fever.

ANTITOXIN IN THE TREATMENT OF SCARLET FEVER

During the last two years we have administered antitoxin to thirty-four severe septic or toxic cases of scarlet fever. We have not used antitoxin in the mild cases, as our previous experience in the old Contagious Hospital had shown that we did not obtain results from its use in the mild cases and that the serum sickness which followed often was worse than the disease itself.

Thesis presented before the Minnesota Academy of Medicine, ember 12, 1930.

In all cases in which we used antitoxin in the first three days of the disease the results have been gratifying; some have almost been spectacular, others showed a moderate to a marked improvement in twenty-four hours.

ILLUSTRATIVE CASES

A. Those treated early before the fourth day of the disease:

Case 1.—G. B., aged sixteen years, entered the hospital on the third day of the disease with a temperature of 104 and pulse of 140. A generalized eruption was present over the entire body. The patient was toxic and the throat very congested. On admission 150,000 skin test doses were administered. In twenty-four hours the temperature was 99.2 and the rash almost faded. Uneventful recovery without complications followed.

Case 2.—T. H., aged seven years, entered the hospital on the second day of the disease with a temperature of 105 and pulse of 130. A moderately severe rash was present but the patient was very toxic and delirious. On admission 150,000 skin test doses were administered. In twenty-four hours the rash was fading, the throat much improved and the temperature 101. The patient made an uneventful recovery and left the hospital on the twenty-fourth day.

B. Those receiving antitoxin after the fourth day:

Case 1.—P. N., aged 22 months, entered the hospital on the fifth day of the disease with a temperature of 105.6 and a pulse of 140. The rash was fading but the patient was very toxic with a septic throat. At once 150,000 skin test doses were administered. Examination twenty-four hours afterwards showed not much change in the throat, but the temperature had dropped to 102. A bilateral suppurative adenitis developed which required incision and healed in three weeks.

Case 2.—C. S., aged six years, entered the hospital on the sixth day of the disease with a temperature of 106 and pulse of 140. The patient was delirious and had a septic throat with marked adenitis. Twenty-four hours after the administration of 300,000 skin test doses the temperature was reduced to 100, but the patient remained delirious. Blood culture taken at this time showed a hemolytic streptococcus, and the patient died three days after entering the hospital.

COMMENT

These four cases typical of our series are presented to show the uniformly good results obtained from the administration of scarlet fever antitoxin early in the disease, and the varied and indefinite results if administered after the third day.

In the group treated before the fourth day there were no deaths. Complications that were not present on admission occurred in only 7 per cent of the cases, and these were either otitis media or adenitis.

Serum sickness occurred in 23 per cent of our cases receiving antitoxin.

On account of the universal use of diphtheria toxin-antitoxin, we have made it a routine procedure to first administer 0.5 c.c. of the antitoxin subcutaneously to desensitize the child, and if there is no reaction to follow in two to four hours, with the rest of the dose.

Of the patients who received 0.5 c.c. of antitoxin subcutaneously, only one had anaphylactic shock, a boy who never had had toxin-antitoxin and on whom we had tried the blanch-extinction test to establish our diagnosis.

In our experience we have never been able to demonstrate any relationship between the degree of anaphylactic shock and serum sickness, and the previous administration of toxin-antitoxin. If we found that we were getting more than the normal amount of serum sickness, investigation showed it to be due to some quality in the serum used, generally that it was not properly aged.

ANTITOXIN IN THE PROPHYLAXIS OF SCARLET FEVER

My experience with scarlet fever antitoxin in the attempt to develop a passive immunity in cases exposed to scarlet fever has been confined exclusively to private practice.

As a whole, my experience has not shown antitoxin to be satisfactory. In some cases it has not developed an immediate immunity and the exposed individual has developed scarlet fever; others may have developed a short immunity but contracted the disease within one year. The most objectionable feature was the serum sickness which followed. Some of these reactions were mild, but in many instances the patient suffered more than he would have if he had developed the disease. In two instances the reaction was extremely severe; in one the patient died. This was a girl of four years who was exposed to her sister who had a very mild or suspicious case of scarlet fever. A prophylactic dose of antitoxin was administered by the family physician. On the fifth day after receiving the antitoxin she developed an urticaria with adenopathy and toxemia. This became steadily worse until death occurred on the tenth day. A very exhaustive postmortem examination revealed nothing but a general adenopathy, especially of the pelvis and abdomen.

We believe that no definite evidence has developed from our experience to justify the use of scarlet fever antitoxin to develop a passive immunity; in fact, several biological houses have withdrawn the prophylactic dose from the market.

ANTITOXIN IN THE DIAGNOSIS OF SCARLET FEVER

The Schultz-Charlton reaction or blanching test has been a definite aid in diagnosis of some doubtful cases of scarlet fever.

The reaction is brought about by the intradermal injection of 0.5 c.c. of scarlet fever antitoxin where the rash is well marked, such as on the chest, abdomen or thigh. Twenty-four hours afterwards, if the case is scarlet fever, a blanching of the skin around the site of injection occurs.

Before the advent of antitoxin we used convalescent serum, but the reaction was not always so striking.

This test will not help a great deal in the mild cases, because we must have a distinct rash to bring out the reaction, but it has been a definite aid in differentiating erythemas and drug rashes from scarlet fever.

SUMMARY AND CONCLUSION

I appreciate the fact that thirty-four cases is a very small group from which to draw any definite conclusions as to the value of scarlet fever antitoxin as a therapeutic agent, and that many cases have to be treated before we know its exact value; also that during these two years the city mortality rate was very low. Of 1,188 cases occurring in the city during this period there were only nine deaths, a mortality rate of 0.76 per cent.

We have administered antitoxin to a great many more patients, especially when antitoxin was first introduced. Then it was given almost routinely in hospital and private cases. We have no exact records but the results were similar to this group of which I have made a more critical study.

To offset the mildness of the present type of scarlet fever, we gave antitoxin to only the septic or toxic cases. We have a working rule in the hospital that if the temperature is not over 102.5, or if the patient is not septic or toxic, we will not administer antitoxin.

1. Thirty-four septic or toxic cases of scarlet fever treated with scarlet fever antitoxin in the Contagious Department of the Ancker Hospital, St. Paul, during the last two years were observed. Of these, four representative cases are reported.

2. All patients receiving antitoxin before the fourth day recovered. Only 7.5 per cent developed complications, and these were adenitis and otitis media. Twenty-three per cent of all patients receiving antitoxin had a serum sickness, a few reactions being moderately severe, but the majority mild.

3. We believe that scarlet fever antitoxin is a specific and prompt cure for uncomplicated scarlet fever if given early, and should be used promptly in all cases that are septic or toxic.

4. From our experience with scarlet fever antitoxin as a prophylactic measure we do not feel justified in recommending it as a method of developing a passive immunity; in fact we advise against its use, because: (1) some patients do not become immunized; (2) others lose their immunity in a short time; (3) the reactions in many instances are very severe, one in our experience having proved fatal.

5. In the Schultz-Charlton phenomenon or blanching test we have a distinct aid in differentiating scarlet fever from erythemas and drug rashes. The test is not of much help in the diagnosis of mild cases in which there is only a slight rash.

CONGENITAL HYPERTROPHIC PYLORIC STENOSIS*

Oswald S. Wyatt, M.D., F.A.C.S.
Instructor in Surgery, University of Minnesota
Minneapolis

THE clinical entity of congenital hypertrophic pyloric stenosis has been recognized for a good many years. As early as 1777 Armstrong described the necropsy findings of a case.

H. Beardsley reported the first case in this country in 1841. He described the clinical and necropsy findings in the fifth year of life, symptoms being present in the case from infancy. He noted that "the pylorus was invested with a hard compact substance, or schirrosity, which so completely obstructed the passage into the duodenum, as to admit with the greatest difficulty the finest fluid. The stomach was unusually large and about the thickness of a hog's bladder."

Siemon and Dawosky reported the first case in Germany in 1842 and for the first time called attention to the projectile type of vomiting. Both of these men attributed the stenosis to hypertrophy of the submucosa.

Landerer in 1879 first used the term "congenital pyloric stenosis."

Hirschsprung in 1887 and 1888 presented the clinical findings and created modern interest in this disease of infants. He considered the condition as a primary developmental hyperplasia.

Finkelstein first called attention to the palpable tumor in 1896. Cordua in 1893 reports that the early operations performed were jejunostomy. Later Stiles reports resection of the pylorus and Loreta performed pyloric divulsion through a gastrostomy. None of these operations were generally successful.

Dr. Edmund Cautley in the British Medical Journal for 1898 reported a death in the fifteenth week from vomiting and marasmus. Another infant died in the eighth week. He noted the characteristic symptoms about as described at present. All his reports were of postmortem findings. He noted that symptoms usually began within the first month. In two cases the tumor had been noted during life. Regarding etiology, he suggested that it might result from a redundancy of fetal growth, due to the anxiety of nature to provide an efficient pyloric sphincter. Rolleston, in discussing this paper, said that pylorectomy was the form of surgical treatment most likely to be successful.

In the same year Willey Meyer and Stern reported a case in which a gastro-enterostomy was done. Also in 1898 Lobker reported the first successful enterostomy. This was the operation of choice for nearly fifteen years.

Heinecke-Mikulicz devolved the first pyloroplasty. In 1907 Fredet performed the first successful submucous pyloroplasty, suturing a longitudinal incision transversely. In 1910 Weber performed the same procedure as Fredet, calling it partial pyloroplasty.

As late as 1912 Rammstedt advised omission of the transverse sutures of Fredet and advised leaving the pyloric wound gaping. This operation of Rammstedt's is today accepted as routine surgical treatment for these cases.

ANATOMY

The normal pylorus in infants is a cylinder about 1.5 cm long. The lumen is usually obliterated by folds of mucous membrane. The pylorus has a powerful sphincter containing both circular and longitudinal muscle fibers which are greater here than in any other portion of the stomach. Longitudinal muscle fibers which radiate from the esophagus and pass over the stomach end before they reach the pylorus. A new set of longitudinal fibers arise on the walls of the stomach which form the longitudinal coat for the pylorus. Very few of these fibers pass over into the muscular coat of the duodenum. The deeper longitudinal fibers penetrate the pyloric sphincteric ring. This apparatus is antagonistic to the pyloric sphincteric ring. Thus the ring has a dilator and a constrictor muscle.

ETIOLOGY

In at least 50 per cent of cases the firstborn child is the one affected. Boys suffer from this affection more than girls in the proportion of 8 to 1. Just what is the explanation of the muslar hypertrophy which is responsible for the structive symptoms is a problem. Hirschrung and Cautley advanced the theory that ere is a primary congenital muscular hyperophy in the affected region, and that this is asciated with a secondary increased functional tivity, the combination resulting in a pyloric struction.

---

*Thesis presented before the Minneapolis Surgical Society October 2, 1930.

Thomson maintained that a functional overtivity of the muscle is the primary factor, that e functional error depends upon a want of codination of the normal stimuli, and that the reated forceful contractions of the muscle result a secondary hypertrophy.

Holt believes that hypertrophy precedes spasm d continues long after the spasm has ceased. ost observers believe there is a certain amount spasm also present. The relation of hyperophy and spasm to symptoms remains in chaos.

Still believes that there is a congenital lack of bility in the harmony of gastric and pyloric laxation and contraction. Another theory asmes that hypertrophy is primary and spasm condary.

Downes and Bolling believe that there is a imary developmental hyperplasia of the circumuscle layer of the pyloric canal. They are so of the opinion that hypertrophy always predes spasm, but that not until spasm has been ded do symptoms appear. Likewise, they state at the severity of symptoms is dependent upon e degree of spasm and the amount of obstrucn caused by the hypertrophy. They believe ere is apparently no relationship between the verity of the clinical symptoms and the size of e tumor.

Dent, Greenbaum and MacHaffie consider the perplasia congenital because the condition has en noted in a seven months fetus, and in seval instances a few hours after birth. Associed with the hyperplasia is a secondary ineased functional activity, the combination relting in pyloric obstruction.

Whichever view is accepted we must apprete that the obstruction results from the ineased bulk of the muscular fibers and the powful contractions of the hypertrophied muscle.

PATHOLOGY

The muscular hypertrophy extends proximalfrom the level of the pyloric veins along the mach wall to the region of the incisura angularis. The hypertrophy stops almost abruptly at the first portion of the duodenum. The hypertrophied pylorus has the appearance and feel of a solid tube about 3 cm. in length and varies from 1 to 2 cm. in thickness. In shape it resembles an olive. The consistency is almost that of cartilage and the color is whitish-pink. On section the thickening is found to be due to a hyperplasia of the circular muscle layer. The submucosa is usually edematous; the other layers are unchanged. Fraser believes that the circular pyloric sphincter is not affected by the hypertrophy. The tumor is smooth, glistening and usually freely movable. The amount of hypertrophy and dilatation of the stomach depends upon the stage of the disease and the degree of obstruction.

SYMPTOMS

A previously healthy, breast-fed infant begins to vomit, apparently for no reason, and usually between the second and fourth week. The vomiting persists, becomes forceful and finally projectile. The vomiting usually occurs right after the feeding, but may occur while the infant is at the breast. The amount of vomitus usually represents the entire stomach content. Vomiting may not be present after every feeding but when it does occur the vomitus, if measured, will be found to be greater in amount than the last feeding. The vomiting is unaccompanied by fever and the appetite is unimpaired. Such characteristic vomiting is rare after the sixth week, but I have operated once where the vomiting began in the eighth week and have seen one performed when it began in the sixteenth week.

If the child presents emaciation and dehydration of a moderate degree, gastric peristalsis is visible and in about 50 per cent of instances a tumor is palpable. Frequently the gastric outline is visible before the waves start; then one, two or even three waves may be seen passing across the stomach. The waves simulate a golf ball passing under the surface of the abdomen.

Various authors place different valuations upon the palpation of the tumor as a diagnostic sign. Surely palpation of the tumor is a valuable diagnostic sign, but I do not believe that one should wait for a palpable tumor before making a diagnosis and deciding upon operation. Bolling believes that it is the most important sign and, if sought in the proper manner, can be felt every time. If the abdomen is palpated while the child is feeding, the pylorus can be felt usually just above the umbilicus, sometimes up under the liver and occasionally just below the ensiform process. Bolling, in 611 cases, felt it in all but two cases and only in three cases was the pre-operative diagnosis incorrect. Personally, I have not been able to palpate the tumor in over 50 per cent of cases. If an operation is undertaken and no tumor found, certainly no operative procedure should be carried out on the pylorus.

The secondary symptoms, such as constipation, scanty urine and weight-loss, are merely the result of vomiting. The weight chart is all-important. One infant we observed in the hospital for twelve days, during which time it just held its weight; then it began to lose and an operation was done. The rate of weight-loss is an excellent guide as to the severity of the obstruction. In severe cases the loss will be 50 to 100 gm. per day and if allowed to go from two to six weeks death will usually occur. If the disease has lasted for more than four months the infant will usually recover.

DIAGNOSIS

With the above clinical picture in mind, the diagnosis should be relatively easy. Projectile vomiting, visible gastric peristalsis and palpable pyloric tumor are found in no other condition in infants. The use of the X-ray is not necessary for a diagnosis and yet occasionally in doubtful cases it will be of value. In one case observed there was such a severe cardiospasm with dilated esophagus that pyloric stenosis was simulated, and only by the aid of the X-ray were we able to make a differential diagnosis. When vomiting occurs from birth the X-ray is of aid in ruling out congenital malformations of the duodenum and esophagus.

TREATMENT

The medical management in case of pyloric stenosis consists of one or more of the following: atropine, breast-feeding, gastric lavage and thick cereal feeding. I feel that except in desperate cases a fair trial on medical management should be given. By this I mean an infant in fairly good condition under a pediatrist's care and holding its weight should be given a week or ten days' trial. I do not believe that such treatment should be persisted in if the baby is losing ground or if we have to take it away from the breast. No medical treatment is a substitute for breast milk.

Holt states that non-operative cases show no symptoms after the first year; yet there is the possibility that the condition predisposes to pyloric obstruction in later life.

Strauss maintains that if 80 per cent of the meal has passed through the pylorus in four hours the child does not need an operation. In ten years he has never operated upon a three to four day old infant because in every case, if these infants were kept on the breast for ten days, the symptoms disappeared. These he maintains are cases of pylorospasm and not true hypertrophy. I doubt whether we are justified, in order to avoid an operation, in permitting these infants to lose so much weight at such a critical period in their development that it takes six months to get them back to normal.

PROGNOSIS

The prognosis depends entirely upon the factors present at the time of operation, the preoperative preparation, the post-operative care and the experience of the individual surgeon.

Gladbloom and Spence, studying the records of 163 cases of Bolling, Downes, Holt and Kerley, concluded that: "When symptoms have lasted less than four weeks, the mortality is only one-third as great as when they have lasted four weeks or longer.

"The mortality in artificially fed babies is more than three times that for breast-fed babies.

"In infants weighing 7 pounds or less the mortality was three and a half times as great as in those who weighed more than 7 pounds.

"The mortality increases in direct proportion to the amount of weight lost previous to operation.

"The mortality for breast-fed infants who vomited less than four weeks and who had lost less than 20 per cent of their best weight is almost nil."

Bolling and Downes say this should be less than 3 per cent. In 611 cases they had a mortality of less than 4 per cent and have had a consecutive run of fifty cases without a death.

Babies in fairly good condition after operation are usually out of the hospital in ten to fourteen days.

PREPARATION FOR OPERATION

The proper pre-operative care of these infants s extremely essential for the success of this operation and should always be cerried out in conjunction with a pediatrist. There is no emerency about this operation and infants in poor condition should be given two to three days of pre-operative preparation. Dehydration should be taken care of by enteroclysis and hypodermoclysis of normal saline. Remember that interoclysis is not tolerated well by infants. Intravenous administrations of glucose solution (3 to 5 per cent) should be given in suitable cases. The day preceding operation as much as 10 to 15 ounces may be given in divided doses. Matill and his co-workers demonstrated that the glucose tolerance of these atrophic infants is considerably raised. They found that "the glucose tolerance of the approximately normal infant, as determined by the Woodyatt method, is very likely identical with that of the normal adult, which is 0.8 to 0.9 gm. per kilogram per hour.

"The tolerance of atrophic infants for glucose is considerably greater, varying from 1.4 to 1.8 gm. per kilogram per hour." The body heat should be strictly maintained and transfusions resorted to if deemed necessary, giving 50 to 75 c.c. only at one time.

Before beginning the operation, the infant should be wrapped in cotton batting, the stomach should be evacuated by means of a catheter and the operating table should be warm. Some prefer operating under ether anesthesia; others under local. I feel that when the baby is in good condition general anesthesia is the choice, but when the risk is poor local anesthesia is advisable.

OPERATION

The operation devised by Rammstedt is the one of preference because it is simple, quick and gives excellent results. An upper right rectus incision is made about 3 inches long, which, upon opening the peritoneal cavity, will usually lie over the lower border of the right lobe of the liver. The stomach, which usually presents, is followed along to the plorus, which is delivered through the wound. The hypertrophied pylorus is held between the thumb and forefinger of the left hand. Beginning at the duodenal end of the tumor an incision is made through the bloodless area on the anterior surface. This incision must extend through the peritoneum and superficial muscle fibers across the entire pylorus and slightly up on the stomach wall. Then with a forceps the wound is spread and the muscle fibers torn, first at the stomach end, working down to the duodenal end. The spreading process is continued until the mucosa throughout the entire length of the wound bulges flush with the peritoneum. If the tearing process is maintained at the duodenal end of the wound until the tear begins to circle the duodenum then you are absolutely certain that all the fibers have been torn and none have been overlooked. The transition from hypertrophied pyloric muscle to stomach muscle is gradual and there is little danger of tearing the mucosa at this point. On the other hand, the transition at the duodenal end is abrupt and the greatest caution must be exercised or a perforation of the mucosa will result.

If any bleeding is present it can usually be controlled with hot packs; if not, a fine silk ligature or muscle transplant can be used. It is unnecessary to attempt to cover the wound with omentum. The pylorus is dropped back into the abdominal cavity and the abdominal wall is closed in layers without drainage. Several silkworm sutures are used to prevent post-operative evisceration.

Mixter states that the conservation of body heat and the avoidance of rough handling must be impressed upon the entire hospital staff. Also that speed, gentleness and hemostasis are the essentials for a successful operation.

COMPLICATIONS

Accidental opening of the lumen of the pyloric canal is no doubt the most severe complication of this operation. The mucosa may be opened by cutting, but occasionally it is torn open. I have been fortunate enough never to have cut it, but I have torn it open at the duodenal end of the wound. It is well to remember that the duodenal end presents the abrupt change from hypertrophied muscle to normal muscle and this is the point where the accident is most likely to occur. If this accident should occur, the opening should be sutured with fine silk. Sometimes a small perforation may be overlooked and close scrutiny is necessary. An overlooked perforation means peritonitis and usually death.

Hemorrhage is rare, but with the usual surgical caution regarding hemostasis it should give no trouble.

Post-operative hernia should not occur if the abdominal wall is closed carefully in layers and several silkworm stay sutures used. Contamination of the dressing should be prevented to avoid wound infection.

POST-OPERATIVE CARE

To my mind, the post-operative management in these cases is by far the most important part of the entire procedure and should be done in strict coöperation with a pediatrist.

The head of the bed should be lowered for several hours and body temperature maintained with care. A teaspoonful of castor oil given after twenty-four hours relieves gas and mucus and makes the baby more comfortable. Vomiting during the first twenty-four hours is relieved best by posture and the stomach tube. Hypodermoclysis should be given freely during the first twenty-four hours. Chloral hydrate is excellent to keep the infant quiet during the first twenty-four hours. Water may be given by mouth two to three hours after operation, and diluted breast milk after three to four hours. If the condition of the child permits, it may be returned to the breast in three to four days.

If small frequent feedings are given, the baby as a rule will have no more vomiting. The feeding should be increased about 10 c.c. every day until the required amount is reached. If larger feedings are started, usually the baby will vomit about four times the first day, three the second and so on until the fifth or sixth day, when vomiting ceases. The usual hospital stay is about ten to sixteen days.

RESULTS

Regarding the results of the Rammstedt operation, I am qualified to speak only from a clinical point of view. All of the infants upon whom I have operated have made uneventful recoveries.

Pathological studies of this condition have been made by Martha Wollstein of the New York Babies Hospital, who reports as follows:

"Healing is brought about by the cells of the serosa and submucosa, but the unstriped muscle cells take no part in the process.

"The wound in the pylorus is healed in nine days. The pylorus has become relaxed within two weeks. The stomach has returned to its normal size within a month, and the gap betwee the cut ends of the muscle coats has practicall disappeared in six weeks. In two years, only line of connective tissue fibers separates thes two muscle ends and the stomach is quite normal

"In contrast to the operation of gastro enterostomy, which leaves the pylorus unchanged, the Rammstedt operation cures th pyloric lesion."

Bolling and Downes have followed some o their cases fourteen years and none of them hav shown any evidence of pyloric obstruction or an symptoms referable to the operation. They conclude that careful analysis of operative result proves that there is no interference with norma physiological development.

THE CONTROL OF NARCOTIC ADDICTION

Narcotic addiction is again the focus of an extraordinary amount of attention. The results of investigations concerning the subject are being made public. The taking of narcotics is usually an attempt on the part of some one with little will power to achieve a state of euphoria or artificial happiness. The addict finds withdrawal accompanied by exceedingly unpleasant symptoms and tends to succumb again. Apparently it is possible for an experienced physician to carry an addict through the withdrawal period with relatively little distress. The importance of narcotic preparations should not be under-estimated. Nevertheless there exist in medicine innumerable occasions when one or more of the relatively non-habit-forming sedatives, narcotics, hypnotics and analgesics may be employed to substitute for an opium derivative. A series of articles is to be published in an effort to indicate the relatively few instances demanding the administration of opium or cocaine derivatives and the many available substitutes. It is estimated that under twenty-five per cent of narcotic addiction results from prescriptions by physicians in cases in which such prescribing may not have been absolutely necessary. The physician must try to limit his prescribing of narcotics absolutely to those situations where they are indispensable. The medical use of narcotics in the United States appears to surpass that of any other nation. Efforts are being made to limit the prescribing of narcotics to those instances where their use is indispensable. (Jour. A. M. A., March 14, 1931, p. 862.)

CASE REPORTS

HYPERTHYROIDISM COMPLICATING DIABETES MELLITUS*

R. C. Webb, M.D., F.A.C.S.
Assistant Professor of Surgery, University of Minnesota
Minneapolis

Hyperthyroidism is a disease which fascinates physicians and surgeons extremely. The diagnosis has become very well understood and the treatment though empiric is relatively standardized. The etiology, however, is still obscure. Diabetes mellitus has become more interesting since Banting gave us insulin and both patient and physician find satisfaction in its control. In hyperthyroidism the disturbance in metabolism is that of an increase where the flame of life is excessively fanned. In diabetes mellitus metabolism is impaired due to lack of secretion of another important gland. When these two diseases coexist we find an extremely fascinating situation which is illustrated in the following case report.

Mrs. C. S. was admitted to the Asbury Hospital on July 26, 1928, under the care of Dr. T. A. Peppard. She was thirty years of age, weighed seventy-eight pounds and was five feet, one and one-fourth inches tall. Her occupation was housewife.

She complained of weakness, palpitation, dyspnea on exertion, a good appetite with loss of weight and frequency of urination.

In March, 1927, she had had a cesarean section performed. There had been two previous pregnancies in which the baby had died shortly following birth. She had not felt well during the past fifteen months. Her present complaints began three months before admission following an attack of influenza. Her heart began to beat fast. She became short of breath on exertion and she had been getting progressively weaker and had lost eighteen pounds in weight. Her appetite was very good but she did not get enough to satisfy her. She drank large amounts of water. Her past history was unimportant and her family history was entirely negative.

On physical examination she was found to be a poorly nourished individual with enlarged tonsils, a normal sized but palpable thyroid and a slightly enlarged heart and a lower midline abdominal scar. Her blood pressure was normal and the pulse rate was from 100 to 110 on admission. She was found to be excreting 11 grams of sugar in twenty-four hours when on a diet consisting of 35 grams of carbohydrates, 35 grams of protein and 120 grams of fat. Her blood sugar was .176 and the carbon-dioxide combining power was 58 volumes per cent. The basal metabolic rate was found to be plus 63.

The glycosuria was easily controlled and she became sugar-free after three days of hospital treatment and the blood sugar was normal on the seventh hospital day. She was given Lugol's solution and her diet was increased. On August 8, 1928, the basal metabolism rate had fallen to plus 37. The diet was increased until she started to show sugar, when it was reduced and then increased again and she remained sugar-free with a maximum intake of food. During a period of seven days she was given from 10 to 27 units of insulin daily but otherwise her diabetic condition was controlled by dietetic measures.

On September 7, six weeks after admission and after having been treated with Lugol's solution, she was referred to the writer for operation and a partial thyroidectomy operation was performed. The amount of gland tissue left was estimated as being about the equivalent of one-fourth of a normal lobe. The pathological report showed a lymphocytic infiltration in a few areas, indicating previous activity, but otherwise showed the condition found in hyperthyroidism brought back to normal by treatment with Lugol's solution. Following the operation Dr. Peppard found it necessary to use as much as 50 units of insulin and five days after operation she was constantly sugar-free. Her weight was the same as on admission and she was taking a diet of 48 grams of protein, 98 grams of carbohydrate and 55 grams of fat with a caloric value of 2,000. The basal metabolism on September 24, 1928, was found to be plus 31. A year later, however, on September 10, 1929, the basal metabolic rate was plus 17.

She was discharged from the hospital on September 24, 1928, and at home kept constantly sugar-free, maintaining her weight, and did not need to take insulin.

On July 15, 1929, she developed some furuncles and a rightsided abdominal pain which was diagnosed as appendicitis. On August 7, 1929, she started to vomit, became dizzy, confused and stuporous and was brought into the hospital on August 8, 1929, under the care of Dr. Peppard, suffering from diabetic coma. She was given active treatment and after three days became sugar-free. She was found to be suffering from an acute pyelitis of the right kidney. The diabetes was again controlled and she left the hospital on September 11, 1929, in good condition but requiring insulin in small amounts. She had been getting along very well for one year following thyroidectomy, controlling her diabetes by diet alone until she developed an acute infection which brought about a diabetic coma. After control of the diabetes, her basal metabolism was found to be plus 17 and she was found to require a small amount of insulin.

Subsequent report.

On January 4, 1931, the patient wrote a letter saying hat she had gained thirty-seven pounds and now weighs one hundred fifteen pounds and is actually fat. She has no nervousness or tremor and as far as she knows has no goiter trouble. She does her own housework. She is still taking insulin and requires seven units three times a day in order to remain sugar-free.

---

*Presented before the Minneapolis Surgical Society January 6, 1931.

DISCUSSION

Carnot and Rathery writing in 1912 on Thyroid Hyperplasia in Diabetes reported four cases all with autopsy reports.

Sainton and Gastaud discussed this subject in 1913. They credited Dumontpallier with the first published case in 1847. At that time sixty cases had been reported in the literature where severe diabetes complicated hyperthyroidism. The prognosis was considered grave. Tuberculosis often appeared as a later complication.

Parhon and Nitzulesco in 1926 reported a patient who had an enlarged thyroid without other symptoms. A physician prescribed treatment and the thyroid diminished in size but the patient developed weakness and hunger and thirst and was found to have diabetes mellitus with exophthalmus. The patient was not given surgical treatment and was unable to buy insulin and death ensued in a short time. These authors believed that the treatment for the goiter aggravated the diabetes. It is probable that this goiter was non-toxic and would have had no influence on the diabetes had it been left alone.

In a study of thirty-eight cases of frank diabetes complicated by hyperthyroidism, Wilder in 1926 found that an inconspicous diabetes may be fanned into flame by hyperthyroidism and the insulin requirement is increased. The intensity of the diabetes is reduced by Lugol's solution, paralleling the basal metabolic rate. Thyroidectomy was almost always followed by a gain in tolerance in the diabetes and there were no deaths in the series. In adenomatous goiter with hyperthyroidism, iodine was found to have little or no influence on the course of the diabetes.

Orator in 1927 reported a case of hyperthyroidism and diabetes where insulin therapy had no effect on the diabetes but after thyroidectomy the sugar content of the urine decreased steadily until the patient developed a tolerance of fifty grams of dextrose.

Coller and Huggins in 1927 reported twelve cases from the University of Michigan Hospital treated by operation with one death. Eleven of the patients had adenomatous goiters. In one case following operation the patient developed respiratory difficulties and an emergency tracheotomy was performed. The respiratory difficulties were not relieved, however, until glucose and insulin were given.

SUMMARY

Thyroidectomy will produce a "cure" of the hyperthyroidism when complicated by diabetes mellitus and renders the diabetes easier to handle and at times results in great improvement in carbohydrate tolerance.

Glycosuria frequently occurs in hyperthyroidism and may indicate the presence of a true diabetes. When true diabetes exists the cooperation of surgeon and internist is positively required. Coma may result as a post-operative complication of thyroidectomy when diabetes is present and may be mistaken for tracheal obstruction.

PACHYMENINGITIS HEMORRHAGICA INTERNA

REPORT OF CASE WITH RECOVERY

Robert Rosenthal, M.D.
Saint Paul

Pachymeningitis hemorrhagica interna in infancy is a rather rare disease, and has a high mortality (60 per cent). It seems therefore justifiable to report a case which presented several interesting features and ended with recovery.

History.—The patient, a boy five and a half months old, was admitted to the hospital December 31, 1930.

The mother was in the hospital with tuberculosis, but the patient apparently was not exposed, as he was separated from the mother shortly after birth. The family history is negative otherwise.

The patient was born prematurely (7 months), weighing 5 pounds and 2 ounces. After an initial loss of almost 1 pound he began to gain in weight and was getting along quite nicely. A Mantoux test at twenty-one days of age was negative, as were also a Pirquet test and a second Mantoux four days later. About the middle of December his skin began to show a yellow tinge; this gradually became worse. The stools always had a normal color. At the same time the child began to perspire profusely about the head and slept poorly. The child was taken to a hospital in Minneapolis and stayed there for two weeks. The hemoglobin was found to be 22 per cent on admission and after an intraperitoneal blood transfusion it went up to 30 per cent.

The child never attempted to sit up and the father thought that such attempts caused pain. He also thought that the child's head had been large since birth, although the attending doctor called it normal at the time of delivery and no abnormality was observed on examination at the age of three weeks.

Feedings: Expressed breast milk was fed for the first five days. Since then the child has been artificially fed. Previous to admission he received a formula containing 1,000 c.c. of milk, 250 c.c. water, five tbsp. dextri-maltose. Cereal was fed three times a day. Viosterol MX in orange juice also was given three times a day.

Physical examination.—The patient was a poorly

TABLE I

Date	Spinal Puncture	Cranial Subdural Puncture
1/2	30 c.c. Clear. Pressure increased. Occasional Lympho. Glob. ft. tr. R. B. C. present (traumatic). Sugar 0.11 per cent. Wassermann neg. Colloidal gold, 0011110000.	
1/5	3–5 c.c. Clear. Normal pressure.	
1/8		Dark brown, about ¾ blood and ¼ spinal fluid. 10 or 11 c.c. High pressure. Fluid browner than normal blood and does not become clearer on standing. Full of R.B.C., many normoblasts.
1/10		Pressure high. Still very bloody. Perhaps a little browner. About 20 c.c. removed.
1/19		About 25 c.c. Dark brownish.
1/23	5 c.c. Clear. Glob. 0. Cell count, 0. Sugar 0.09.	Blood degenerating. There are still nucleated R.B.C. No evidence of blood pigment.
1/28		Fluid still quite brown. Contains much less blood.
2/2		The fluid is slightly less brown. Crenated R.B.C.; R.B.C. breaking down. No evidence of blood pigment. The nucleated R.B.C. are more pycnotic. The W.B.C. are large monocytes and lymphocytes. A culture of fluid showed staphyl. alb. (which was considered a contamination).
2/9		Yellow. 12 c.c. Cell count 370. P.M.N. 57. Lymph. 43. Few R. B. C. No organisms. Culture neg.
2/14	5 c.c. Clear. Cell count 5. Wassermann neg.	Yellow. Cell count 44. Some R.B.C. Colloidal gold: 0±±1111+000.

nourished infant, weighing 12 pounds, 9.5 ounces. He was very pale, had a waxy color, and cried much.

The head was quite large, the circumference being 47.6 cm. The fontanelle was large, bulging and very tense; the sagittal suture was gaping. There was some cranio-tabes. The eyes were pushed downward, the upper margin of the iris being visible, the lower third being covered by the lower lid (visus hydrocephalicus).

The chest had a circumference of 42.5 cm. and was normal.

There was nothing abnormal about the throat and abdomen.

The nervous system was normal, except for the enlargement of the head and the increased intracranial pressure.

The skeleton showed a rosary, some thickening of the epiphyses, some craniotabes and a hydrocephalic type of head. There was no tenderness of the extremities.

The urine was normal.

The blood examination showed Hgb. 40 per cent, R. B. C. 2,150,000, P. M. N. 43 per cent, Lymph. 52 per cent, Eos. 3 per cent, Trans. 2 per cent, moderate poikilocytosis, marked anisocytosis, moderate polychromatophilia, several normoblasts.

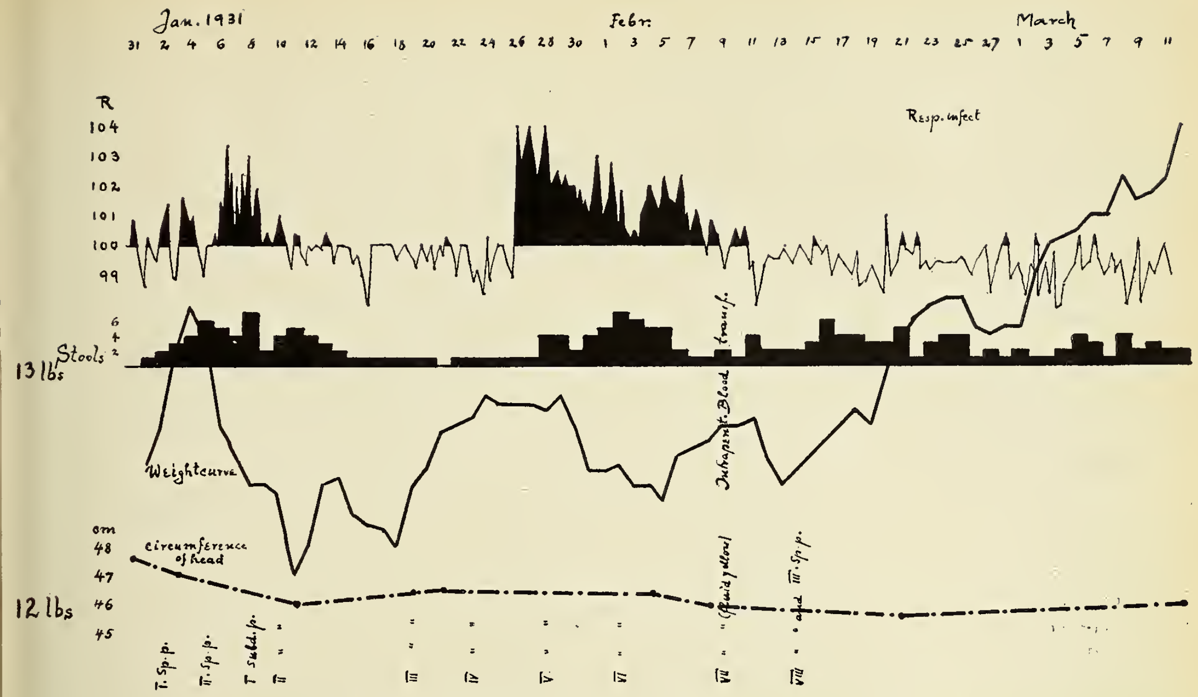
X-ray examination: The head showed thinning of the skull bones and increased separation. The bones of the forearms and legs showed definite changes due to rachitis.

Course of Disease.—January 2, 1931. A spinal puncture was performed and 30 c.c. of clear fluid were obtained under highly increased pressure. The fluid was practically normal otherwise (see table). The fontanelle was much less tense after the puncture and was hardly bulging.

January 5. The circumference of the head remained the same and the fontanelle was bulging again; another spinal puncture was done but only about 4 c.c. were obtained. The pressure was not far from normal. After the puncture the fontanelle seemed slightly softer, but was still bulging.

January 8. The child was worse, ate poorly and vomited much. A ventricular puncture was attempted on the left side but no fluid obtained, but on removal of the needle a very bloody fluid gushed out from the subdural spaces. A subdural cranial puncture in the right corner of the fontanelle produced the same fluid, which contained much fresh blood with many normoblasts, but no pigmented phagocytes. On standing the fluid did not become clearer. It was estimated that the fluid contained approximately three-fourths blood and one-fourth spinal fluid, and it was definitely somewhat browner than normal blood. The fontanelle, which was very tense before the puncture, was slightly sunken afterwards. Examination of the fundi revealed "bilateral chorio-retinitis. No hemorrhages of any consequence."

January 10. The child was very pale, listless and drowsy, but vomited less. A second subdural puncture



This chart shows the temperature curve, the weight curve, the curve of the circumference of the head and the numher of stools. The response of the intestinal tract to the rise of temperature (parenteral dystrophy) is interesting. The spinal and suhdural punctures respectively are given at the bottom of the chart.

was performed and 10–12 c.c. of very bloody fluid removed, which was perhaps a little browner; the pressure was markedly increased.

January 12. The child cried frequently, but began to eat better and vomited only occasionally. The temperature, which had been as high as 103.5 for the past few days, became lower. A blood count showed: R.B.C. 3,140,000, several normoblasts, P.M.N. 24 per cent, monocytes 2 per cent, Eos. 3 per cent, moderate anisocytosis, some poikilocytosis, slight polychromatophilia. The circumference of the head was decreased 1.5. cm.

January 19. Five days ago a decided improvement could be noticed; the patient became brighter and began to eat much better. The temperature was not over 100 for the last four days. A third subdural puncture yielded 25 c.c. of dark brownish fluid. This fluid was decidedly browner, but contained less blood.

January 21. Another examination of the fundi: "No retinal hemorrhage. Marked chorio-retinitis." The fontanelle was not bulging. The circumference of the head remained the same. The bleeding time was 3 minutes, 20 seconds, and the coagulation time 6 minutes, 5 seconds.

January 23. A second spinal puncture was performed and a perfectly normal fluid obtained, while the subdural fluid was still dark brown and under quite high pressure. In general, the child was improving. An X-ray examination of all extremities showed a mild rachitic involvement of the bones, and "there is an area of decreased density just proximal to the epiphyseal line in the right radius, which may possibly be a manifestation of associated scurvy."

January 27. Yesterday the temperature went up again (104 R.) and remained high. The child became very fussy; the examination was negative except for the head findings and rather frequent and loose stools (parenteral dystrophy).

January 28. The subdural fluid remained quite brown, but contained much less blood; the pressure was fairly high.

February 2. The fever was less severe in the last few days. The child had five to six stools a day and dropped in weight. The circumference of the head remained stationary (46.5 cm.) and there was occasional vomiting. The urine contained a trace of bile. A blood examination showed: Hgb. 51 per cent, R.B.C. 2,830,000. The subdural fluid was still brown.

February 7. The child became fussy again. There had been another rise of temperature during the last three days (102.5-103 R.).

February 9. As the child was still very anemic, an intraperitoneal blood transfusion (father's blood, 200 c.c.) was given. The temperature had decreased during the past two days, the stools became better and the child began to gain in weight. The subdural fluid became yellow since the last puncture, but the cell count was fairly high (see table).

February 13. A spinal puncture yielded clear, normal fluid. The subdural fluid (eighth puncture) was light yellow, and the cell count greatly reduced. The blood had slightly improved: Hgb. 53 per cent, R.B.C. 3,220,000, W.B.C. 8,450; Diff.: P.M.N. 44 per cent, Lymph 56 per cent, and the child seemed improved in every way.

Febuary 24. The patient was gaining in weight (12 ounces in last ten days). Occasionally the temperature was slightly elevated (100.5 to 101 R.). The circumference of the head remained stationary; the fontanelle rather sunken. The patient contracted a moderately severe respiratory infection. The hemoglobin was 55 per cent, the R.B.C. 3,580,000.

March 17. The child continued to improve in spite of the respiratory infection and a mild impetigo. The circumference of the head remained stationary; the fontanelle was rather sunken. The hemoglobin increased to 65 per cent and the last R.B.C. count was 3,350,000. The child was still unable to hold up the head. Examination of the nervous system was negative. The physical condition had decidedly improved. The weight had increased rapidly (1.5 pounds in the past month). There were signs of mild rachitis.

COMMENT

On first examination this child appeared to have a hydrocephalus internus until the subdural puncture led to the correct diagnosis. The spinal fluid remained normal throughout the sickness while there was a dark brownish, very bloody subdural fluid over the convexity of the brain which later changed to the typical yellow color. No retinal hemorrhages which are so frequently present in pachymeningitis were found, but there was a chorioretinitis.

The etiology in this case is not clear; no evidence of a severe rhinitis could be found in the history. Whether the severe secondary anemia was caused by the pachymeningitis, or rather was due to the same factor causing the pachymeningitis, could not be ascertained. The peculiar X-ray findings, which make one suspect a mild scurvy, may be of importance. A relationship between scurvy and hemorrhagic pachymeningitis has been suspected as early as ten or more years ago, but it has not been possible to prove it. In this case, however, the X-ray findings (besides the rachitic changes) are so mild and indistinct as not to permit an exact diagnosis.

This case belongs in Group I of the types of pachymeningitis hemorrhagica in infancy, as described by Rosenberg (Berlin, 1913). This is the type with a slow onset, running a course like an internal hydrocephalus, with very few symptoms from the central nervous system. The second period of high fever in this case was a rather unusual feature.

The subdural punctures were continued at first to reduce the highly increased intracranial pressure, and later only small amounts were withdrawn for the purpose of controlling the changes in the subdural fluid. The anemia was treated with iron and one intraperitoneal blood transfusion. A diet high in vitamins was given. There was a definite improvement.

The prognosis in this case seems quite good. No recurrence of hemorrhages was observed; the intracranial pressure returned to normal and no abnormal increase in the size of the head was noticed for more than one month after the last subdural puncture. That the child was unable to hold up the head or sit up when over seven months old is due in part to the mild rachitis as well as to a peculiar debility which is very frequently found after a pachymeningitis. The prognosis as to the mentality has to be somewhat guarded because a certain percentage of such children who recover have been found to be mentally retarded when examined several years later.

BILATERAL SPONTANEOUS PNEUMOTHORAX: REPORT OF A CASE*

Harry G. Wood, M.D.
Rochester, Minnesota

The exact percentage of cases of recurring attacks of spontaneous pneumothorax is difficult to determine accurately. In a series of seventy-one patients observed in The Mayo Clinic, 21 per cent gave a definite history of multiple attacks, and an additional 24 per cent gave an indeterminate history strongly suggestive of previous spontaneous pneumothorax. In 11 per cent of the series both a right-sided and a left-sided spontaneous pneumothorax had occurred at different periods, but in only three cases, approximately 4 per cent, had bilateral pneumothorax occurred simultaneously or with such a short interval that both sides showed partial collapse at the same time. The case reported here is illustrative.

A man, aged thirty years, who came to the clinic September 17, 1930, gave a history of having been apparently perfectly healthy until the age of fifteen years. Then he had an attack of sudden sharp cutting pain throughout the entire pulmonary area, most severe in the upper part of the thorax and shoulders. The pain came with inspiration; there was no pain while he was holding his breath. There was moderate cough and expectoration and some dyspnea. One treatment with a therapeutic lamp gave immediate and complete relief. The patient felt well and apparently remained in excellent health for ten years following this episode. The family history was negative for tuberculosis. The patient had been a heavy cigarette smoker and had had a chronic cough and expectoration for the last ten years. He remembered one attack of pain in the thorax about six years before admission similar to the one occurring at the age of fifteen years. This was relieved by strapping the thorax. Five years before admission, there was moderate hemoptysis on one occasion, but no history of bleeding otherwise. Further attacks of pain in the thorax had not occurred until two years previous to examination. Since then, at least five attacks have occurred, four of which were in the left side of the thorax; the other was in the right side. There were numerous other less severe attacks which may or may not have been associated with partial pneumothorax. Fever, sweating or effusion was not present. The outstanding symptoms with all attacks were pain and dyspnea with increased irritative cough and little expectoration. The pain generally began in the precordial area; became general throughout the thorax and radiated to the shoulder. It generally lasted two or three days; the dyspnea lasted from eight to ten days and there had been complete subjective relief in three to four weeks. Various diagnoses had been made, but only one roentgenogram of the thorax had been made, about ten months before admission. This showed some infiltration of both the right and left apex but no pneumothorax. The patient had been working hard and had lost weight. He stated that he tired easily. He had been made to rest more and had been placed on a supernourishing diet. In a period of three months he gained 25 pounds. Seven days before admission, without exertion, there was a sudden onset of the usual symptoms: pain, dyspnea, cough and some expectoration. He continued working part time and driving his car for six days.

---

*From the Division of Medicine, The Mayo Clinic, Rochester, Minnesota. Submitted for publication April 1, 1931.

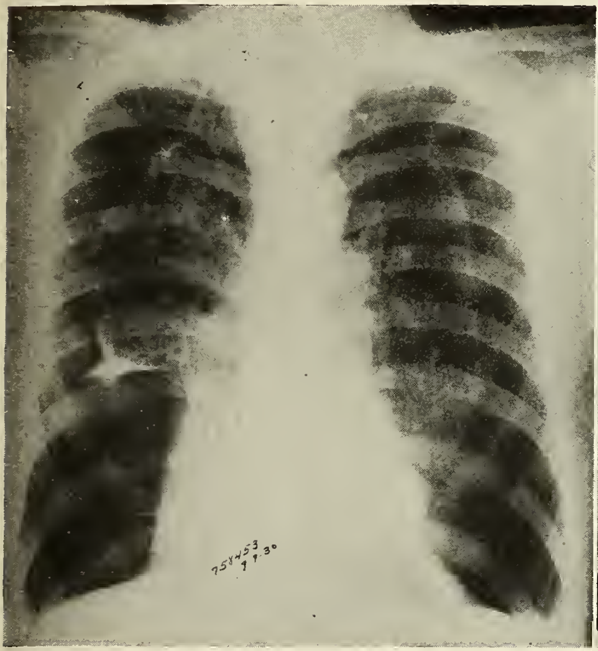


Fig. 1. Bilateral pneumothorax with multiple pleuritic adhesions on the right and definite circular line in the right lower part of the thorax, suggestive of a large emphysematous bleb replacing the right lower lobe.

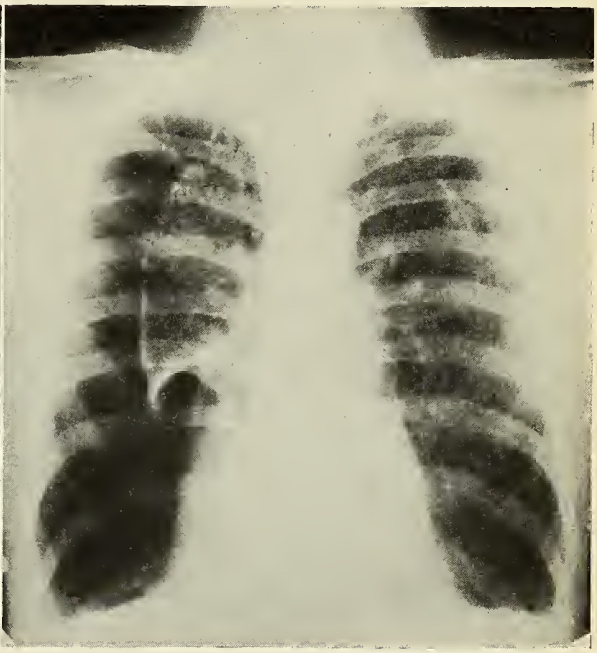

Fig. 2. Recurrent pneumothorax of the right side.

At examination in the clinic the patient looked sick; he had an anxious facial expression, he was definitely dyspneic and seemed to be in some pain. Both temperature and pulse were normal. The percussion note was hyperresonant throughout the entire pulmonary area, with marked suppression of the breath sounds, and vocal fremitus and vocal resonance were almost absent. There was no tinkle, no succussion and no coin sound. The roentgenogram of the thorax (Fig. 1) showed bilateral pneumothorax with multiple pleuritic adhesions on the right. The right lung was collapsed to approximately a fourth and the left to a half its normal volume. In this roentgenogram there was also a definite circular line showing in the right lower part of the thorax, suggestive of a large emphysematous bleb replacing the right lower lobe. Although a small amount of fluid was manifest at both costophrenic angles by roentgen-ray examination for a few days, it soon disappeared and the patient made fairly rapid subjective and objective improvement until September 27. At this time, he laughed heartily, a coughing spell followed and he became quite dyspneic, but had no pain. A roentgenogram of the thorax (Fig. 2) September 29 showed absence of the circular line in the right lower part of the thorax and increased collapse of the right lung. Apparently there had been a rupture of this cyst. The patient improved rapidly following this fresh pneumothorax, with rapid expansion of both lungs, but with recurrence of a large cyst of the right lower lobe (Fig. 3). October 18, a few minutes after slight exertion, there was sudden severe pain throughout the entire thorax and rapidly increasing dyspnea and cyanosis. The patient soon became comatose. He was placed in an oxygen chamber and both thoracic cavities were aspirated; 650 c.c. of air was removed from the left side of the thorax and 400 c.c. from the right. He immediately regained consciousness and there was gradual but continued objective and subjective improvement until he was well enough to go to Tucson for sanitarium treatment five weeks later. At this time, the right lung was completely reëxpanded with no evidence of cystic lower lobe. The left lung was almost completely expanded save for a small area of localized retraction at the apex, presumably due to adhesions.

During the period of three months that the patient remained under observation, there was no elevation of temperature or pulse and numerous examinations of sputum failed to reveal the presence of the bacillus of tuberculosis. Coincident with the expansion of the lungs, definite infiltration of both upper lobes became manifest. During the last month of observation, there was a definite increase in the extent of infiltration in the right upper lobe, with development of cavitation. The Wassermann reaction of the blood was negative and the patient maintained a high normal blood count throughout. Granular casts were found on two occasions. Moderate chronic prostatitis was present. There was no evidence of renal tuberculosis.

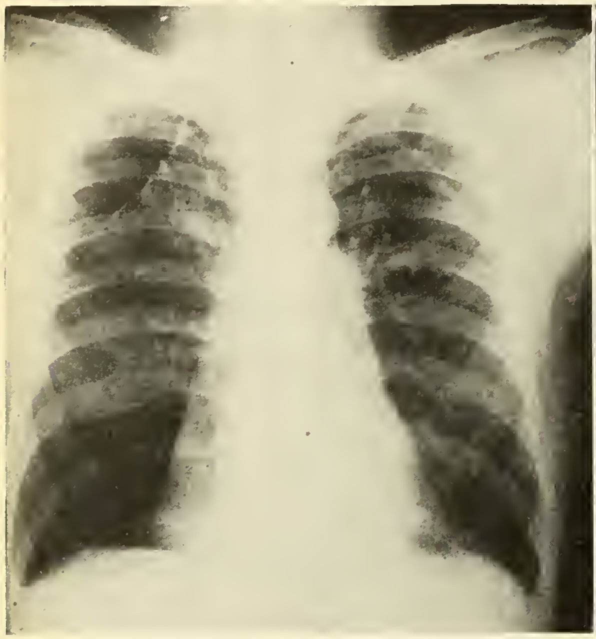

Fig. 3. Recurrence of emphysematous cyst of right lower lobe following recurrent pneumothorax.

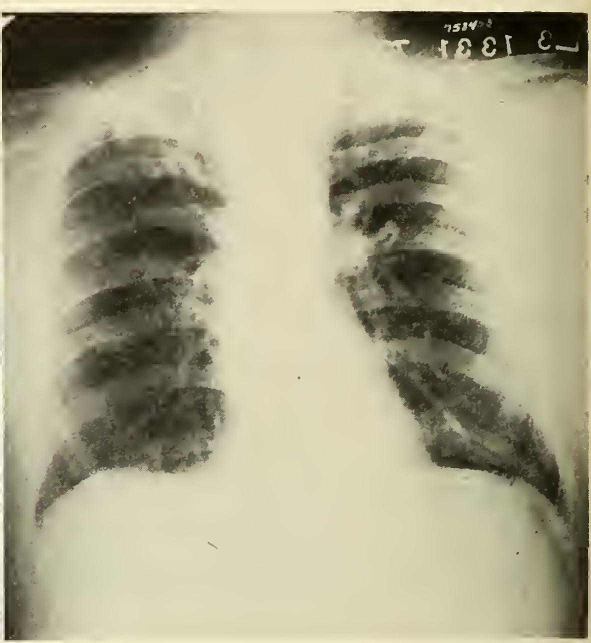

Fig. 4. Complete expansion of both lungs with improvement of the tuberculous process.

The patient complained greatly of abdominal distention with indefinite pains and soreness, but roentgenray examination of the gastro-intestinal tract was negative; the symptoms were apparently reflex in origin.

During the last three months, this patient has had sanitarium care at Tucson and has improved steadily. There has been no recurrence of pneumothorax. Roentgenograms were made March 13 (Fig. 4) and are reproduced here by courtesy of his physician, Dr. Samuel H. Watson. They show complete expansion of both lungs with a definitely lessened amount of infiltration, showing apparent obliteration of the cavity.

There are many points in this case of unusual interest. The initial spontaneous pneumothorax occurred fifteen years ago. There has been an indeterminate number of attacks since. Both sides have been involved simultaneously on at least two different occasions. The last time, the collapse was so extreme as rapidly to cause unconsciousness and there is no question that death would have followed without immediate decompression.

Definite pulmonary tuberculosis is present, and tuberculosis must be accepted as an etiologic factor. Nevertheless, frequently recurring attacks of spontaneous pneumothorax over a period of years, without temperature or occurrence of definite effusion, is more characteristic of the so-called idiopathic nontuberculous type of disease. The cystic changes occurring in the right lower lobe with rupture and recurrence of cyst are hard to explain on the basis of pleural tuberculosis. The possibility that there is more than one etiologic factor must be considered. It is probable that this patient has congenital pleural imperfections and that this condition as well as pleural tuberculosis has been responsible for the frequently recurring spontaneous pneumothorax.

SARCOMA OF THE THROAT*

REPORT OF TWO CASES

J. A. Watson, M.D.
Minneapolis

Case 1.—G. K., a male, aged 22, consulted me March 5, 1926. He first noticed in May of 1925 that his throat had commenced to hurt on swallowing. In June he had his tonsils removed, after which he kept coughing up masses of fleshy material. He had radium treatment at a certain clinic during that summer and lost about twenty pounds in weight through not being able to swallow. The diagnosis at the clinic was cancer of the throat.

---

*Read before the Minnesota Academy of Ophthalmology and Otolaryngology, Minneapolis, January 9, 1931.

Previous to this illness he had never been sick, except for measles when he was twelve years old. He very seldom had colds or coughs, had always been strong and able to work hard on the farm. The family history was entirely negative. His mother had died at fifty-one of appendicitis, his father and four sisters were all living and all in good health. The examination of the throat revealed great numbers of masses of a polypoid appearance clustered around the upper and posterior rim of the larynx and greatly resembling nasal polypi. They covered entirely the arytenoid region, one or two of the masses hanging down into the cavity of the larynx, but not reaching to any depth there. The whole right pyriform fossa was filled with large masses of the growth, giving the impression that they originated in this region.

Two specimens were removed for microscopic examination, one from the region of the right pyriform fossa, the other from the neighborhood of the left arytenoid. Smears were also taken. There were found in the smears and sections large numbers of fungoid organisms which Dr. Henrici and Dr. C. J. Watson of the University identified as Citromyces. Dr. E. T. Bell's report was as follows: "I have examined several sections of the growth from the larynx of G. K. The specimens invariably show an abundant granulation tissue growth, but I have never seen any evidence of carcinoma. The fungi repeatedly found are in my opinion the cause of this unusual growth."

Dr. Leo G. Rigler reported on the X-ray examination as follows: "The patient is of the asthenic type. The bony thorax is normal. The diaphragm movements are free and equal. The trachea is in the midline. The cardiac shadow is normal in size, shape and position for this type of individual. The hilus shadows are considerably thickened. The linear markings are moderately increased, especially in the right lower lobe.

"There is evidence of interlobar pleurisy between the middle and upper lobes on the right side of very slight extent.

"Right Lung: The apex and upper lung field is clear. In the lower portion of the right lung there is a number of small nodular shadows about 2 mm. in diameter and one large nodular shadow which is anterior and out near the periphery about 0.5 cm. in diameter.

"The exact nature of these shadows is not entirely clear. They are rather dense and might correspond to a healed tuberculosis. They could, however, be associated with aspergillosis, although there is no evidence of cavitation such as usually occurs in this condition.

"Left Lung: The apex and outer lung fields are clear.

"Conclusion: Nodular lesion, right lower lobe. Etiology not clear."

On March 19 it was apparent that something must be done to save the patient from death by inanition, if not by asphyxia, as he was unable to swallow and there were times when there was a certain amount of dyspnea. Consequently, large amounts of the pathological tissue were removed, the work being done under indirect laryngoscopy. There was very little bleeding; most of the growth was bitten away by forceps. Within a week the growth was nearly as large as before and it was necessary to repeat the procedure many times in order to give the patient some relief. Radium and X-ray therapy were both used without result. Repeated microscopic examinations of the growth always brought a report to the same effect, namely, abundant granulation tissue, but without any evidence of malignancy. Numerous specimens, large and small, from all portions of the growth were submitted, and there was always an abundance of Citromyces. Because the patient was evidently doomed without some more radical procedure and because so far it had been impossible to find any tissue which gave microscopic evidence of malignancy, access was finally gained to the throat by means of a pharyngotomy. After tracheotomy and the insertion of a tube, the hyoid bone was divided in the center by a vertical incision, from the upper end of which a horizontal incision was made reaching to the anterior border of the sterno-hyoid muscle. By careful dissection through the depths of the neck and retraction of the triangular flap, it was possible to gain good access to the throat. All of the growth apparently was removed by means of the diathermy knife. In the depths of the pyriform fossa, however, one was so close to the carotid vessels—the pulsation of which could be felt under the finger with apparently almost no intervening tissue—that there was from the beginning doubt as to complete eradication in that direction. The rest of the growth was followed and as was hoped, destroyed everywhere. The tracheotomy wound was kept open for many weeks. The patient recovered satisfactorily and for a long time the outlook seemed hopeful. In about two and one-half months recurrence was evident in the depths of the right pyriform fossa, and it was not long until the same tedious and disagreeable process of removing masses piecemeal in order to prolong the patient's life was, perforce, resorted to.

In January of 1927 the patient returned to the clinic, where he had been first treated, for inspection, and I received a letter from them stating that they had again examined the tissue which I had sent with the patient and that the diagnosis was carcinoma, grade four, the same as at the time of the original examination. The conflicting reports were most puzzling, especially in view of the history and clinical course of the disease. The man's age, twenty-two, was certainly against the growth being carcinomatous. The fact that even after the last year and a half of observation, nearly a year of it by myself and my partners, there was at no time any evidence of involvement of the cervical glands, was still more strongly against the probability of the condition being carcinomatous. Specimens were again sent to Dr. Bell, who now reported that the growth was certainly not carcinoma, but that there were evidences in the later specimens of commencing sarcomatous degeneration. The issue being joined, a quantity of specimens was sent to Dr. James Ewing at the department of Pathology, Cornell University Medical College. Some of these were specimens taken early in the history of the case, others those taken later. Dr. Ewing's report follows: "In the case of G. K. sections of tumor of the larynx which you send me show a very cellular myxosarcoma. In the sections taken a year ago, I find nothing but granulation tissue, or chronic inflammation of the submucosa. In all the other sections and especially in the last one, number five, there is a very cellular and large oval cell tumor which surrounds blood vessels and shows the typical structure of nasopharyngeal myxosarcoma.

"In my experience this is a very malignant tumor and very few cases are cured. Burnham and Kelly's Institute seems to have cured one case by keeping up small external applications of radium for a year or more. This case is reported in the "Archives of Surgery," 1923, 6:429. We have lost several cases at the Memorial Hospital by attempting to destroy the tumor by surgery or caustic radium. We now have some cases under treatment by repeated moderate doses of external radiation. If you attempt to remove or cauterize these cases, they eventually become infected and die from sepsis or hemorrhage, whereas slower restraint to growth can somtimes be obtained by the less violent radiation methods."

In this case, however, hemorrhage was not the cause of the eventual death, and, while sepsis played some part in the production of the exitus, the patient died mainly as a result of inanition, as for some weeks before the end it was almost impossible to administer nourishment or even water. The growth extended downwards into the esophagus and even involved the tracheotomy wound, though it was possible to keep the tracheotomy tube clear until the last.

Case 2.—Mrs. E. I first saw this patient on July 23, 1928. Nine or ten months previously she first experienced a feeling of not being able to breathe or swallow on lying down. She had since been under treatment with radium and local applications, but no exact diagnosis had been made. A laboratory examination by Dr. Bell of the University had shown granulomatous tissue only. A growth had been discerned by her family physician on the right side of the throat. The Wassermann and all other tests were negative. My partner, Dr. W. E. Patterson, had seen the patient in consultation during my absence from the city; he believed it to be malignant and I agreed with him on my first examination.

Examination disclosed a large mass protruding from the right side of the hypo-pharynx in the upper part of the pyriform fossa. The tissue appeared to be of firmer consistency than in the former case. There was considerable infiltration of the pharyngeal wall around the protruding portion of the growth, which was large enough to produce some pressure against the larynx and epiglottis. There was very little appearance of redness or congestion of the mucous membrane. The growth was sessile and larger than one-half the size of a walnut; there was no involvement of the cervical glands.

The patient's general health was good. Physical examination disclosed nothing of importance. She had been having some pain in the right side of her throat and in the right ear, and the act of swallowing produced considerable discomfort.

At my suggestion she was referred to a prominent Chicago laryngologist for consultation. He believed the tissue to be granulomatous and non-malignant and proceded to remove it by electro-coagulation. He submitted the tissue to microscopic examination and was confirmed in his opinion of non-malignancy, writing us a letter to that effect. An examination, however, of later sections caused his pathologist to change his mind and a second letter reported that the former opinion had been revised, the growth now proving to be fibrosarcoma.

In March of 1929 the patient came to my office. There was a large scar at the site of the growth and I feared that there were signs of recurrence. When she next returned, in about six weeks or two months, there was a very considerable mass with odor and discharge. I advised her to return to Chicago. Since that time several operations have been done by means of electrocoagulation, the growth always showing an invincible tendency to recur.

Sarcoma of the throat is certainly rare as compared with carcinoma. It occurs much earlier in life as a rule than the latter disease, which is a diagnostic point that should be taken into consideration. In sarcoma the cervical glands are rarely involved, or, if at all, not until late. In the history of intrinsic carcinoma of the larynx, they are almost always involved before the disease has run any very lengthened course. This observation as to glandular involvement is, of course, equally true of the two diseases in other parts of the body.

There are certain lessons to be drawn from these two cases. Even though the microscope shows no malignancy, all so called granulomatous tissue in the throat should be looked upon with extreme suspicion. Negative microscopic evidence should certainly never be taken as conclusive in the face of any persistent mass, in this situation at least. I think that the very term granulation tissue should make a more exact diagnosis imperative. Granulation tissue has an underlying cause and it is early in the history of such masses that the cause must be found. If they do not yield very readily to mild local applications, if there is no reason to suspect any local inflammatory condition, no increased leukocyte count, no elevated temperature, no benign cyst formation, no positive Wassermann, no evidence of tuberculosis, and in short no apparent reason for it, the mass should be considered malignant, in spite of a microscopic diagnosis of "granuloma" or "granulation tissue growth."

Such a diagnosis of malignancy, even though it be more tentative than positive, having been made, the question of treatment arises. I believe that sarcomatous growths in the throat are almost hopeless, yet it has always seemed to me that in the first of these two cases, even though the very radical procedure of pharyngotomy and the diathermy knife was undertaken at a late stage in the history of the disease, it came within a measurable distance of a cure. Furthermore, I believe that he might even have been cured had it not been for a very close proximity of the growth to the great vessels of the neck. Possibly the vessels should have been ligated, but at the time of operation he was in no condition for it, and there was ground for hoping that the eradication was complete.

It is true that the primary site of the growth in this particular case may have been very close to the great vessels and that even if that very radical procedure had been undertaken a year or more before it was, it could not then have been eradicated. Nevertheless, I feel that valuable time was lost by temporizing with the condition. In the second case, profiting from my experience in the first, and in view of the fact that radium had already been repeatedly tried, I advised the friends to choose between one of two courses: first, to leave the growth entirely alone with the possible continuation of radium treatment or, second, to resort to the radical procedure of pharyngotomy. I believe that my advice was justified by the outcome, as the condition has become manifestly hopeless. The disease has invaded the bodies of the fourth and fifth cervical vertebræ. The patient is breathing through a tracheotomy tube and is being fed through an artificial opening into the stomach.

DOUBLE BRANCHIAL CYSTS COMPLICATED BY CARCINOMA OF THE LARYNX*

Arthur L. Herman, M.D.
Minneapolis

The following case has two independent features, each of which is important for different reasons. The first is the branchiogenic nature of a carcinoma of the larynx, to which a review of the literature shows no parallel. The second is the existence of two branchial cysts on the same side of the neck, the possibility of occurrence of which has been denied according to certain theories regarding the origin of branchial cysts and fistulæ.

The patient, a male, fifty-one years of age, was first seen March 21, 1927, some two months after the onset of symptoms. These consisted of a hoarseness and tenderness in the left side of the neck and followed an acute coryza.

Twenty years previously the patient had been confined to a tuberculosis sanatorium for several months but had no symptoms of activity since. He had had a gastro-enterostomy performed one year previously for a duodenal ulcer. At that time no masses were noted in the neck. His wife had died of a luetic aortitis.

Upon examination the tonsils and pillars were found to be injected. The deep cervical glands on the left were very hard and fixed. Two certainly, and possibly three, were noted. From the character of the glands malignancy was suggested.

The left vocal cord was found to be immobile. There was a smooth, elevated, reddened mass in the left recessus piriformis over which the mucous membrane was intact. X-ray of the chest was normal in appearance and the Wassermann was negative.

On the basis of these preliminary findings, the most likely diagnosis seemed to be carcinoma of the pyriform sinus, with metastases to the deep cervical glands.

Supporting this diagnosis were the age of the patient, the nature of the onset of the disease and the character of the masses palpated on the side of the neck.

Because of his confinement in a tuberculosis sanatorium, tuberculosis was considered, although there were no chest findings either on physical or X-ray examination.

Lues was also considered because of the fact that his wife had been infected. However, the Wassermann was negative and there were no other clinical signs suggesting lues.

These were the only possibilities considered at this time.

The possibility of branchial cysts was not even considered, for a branchial cyst has been always described as a single, solitary mass and in this case there were multiple masses. Hamilton Bailey reported a case of branchial cysts which upon section showed numerous tubercle bacilli. Some such bizarre combination perhaps should also have been kept in mind.

On March 25, a biopsy was performed. Upon excising part of the wall of one of the masses, a white, cheesy material escaped under considerable pressure. We fell into the common mistake of thinking we were dealing with a tuberculous lesion. Microscopic section, however, showed a cyst wall and a diagnosis of branchial cyst was made.

It was interesting to note that on the following day the patient's voice was strikingly improved. We explained this by the relief of pressure on the vagus or recurrent laryngeal nerve.

Aphonia due to pressure by branchial cysts have been reported by Carp and Thompson. Carp thought that the aphonia was due to pressure on the vagus. Thompson has reported a case with dysphagia, pain and aphonia, with fixation of the left vocal cord. At operation the cyst was found to be attached to the left lamella of the larynx and the greater cornu of the hyoid. Following the operation there was complete restoration of the voice.

In our case, following this temporary improvement after the biopsy, the voice became gradually worse. By this time we felt that we were dealing with a branchial cyst of the larynx and a separate branchial cyst of the neck.

The question of the proper procedure arose, *i.e.*, whether it would be better after a preliminary tracheotomy to do a section of the larynx and excise the cyst; or to excise the branchial cyst in the neck first and remove the cyst in the larynx at a second operation; or third, to do a tracheotomy and then later to remove both the cysts at one operation.

In deciding upon the procedure to follow, we perhaps allowed ourselves to be unduly influenced by the remarkable relief secured by lessening the pressure in the cyst as a result of the biopsy. It was felt that considerable relief could be obtained by removing the branchial cyst in the neck first and then the cyst in the larynx could be attacked later if the patient was not sufficiently relieved of his symptoms.

---

*Thesis presented before the Minneapolis Surgical Society at the meeting of January 6, 1931.

Accordingly, on June 3, 1927, an incision was made along the anterior border of the sternomastoid. A cyst was found fairly superficially. It was dissected out according to the method described by Hamilton Bailey, *i.e.*, about half the contents were drained off and then the cyst was grasped with a sponge-holder and two small squares of gauze. On making traction, a piriform projection of the cyst was found to run upward. By bluntly dissecting this it was found to run upward between the internal and external carotid arteries and became frayed out just before it reached the region of the tonsil. Further exploration of the neck revealed a second cyst. This cyst had a similar projection which extended horizontally between the jugular vein and the common carotid artery, and seemed to pierce the wall of the larynx. As much as possible of this projection was removed with the cyst. These two cysts were each about two centimeters in diameter. They were entirely separate from one another, one evidently corresponding to a second, and the other to a third branchial cleft derivation. The piriform projection of the upper cyst had the classical relation to the carotid arteries, passing between the internal and external carotids. The tract of the lower, however, passed in front of the carotid instead of behind it as usually described.

When this patient was discharged from the hospital it was noted that his voice had again greatly improved.

A new symptom, pain upon swallowing, appeared during the month following the operation. This pain seemed to be localized in the region of the left tonsil. The left tonsil was seen to gradually enlarge and to project more and more into the pharynx. This pain could be entirely relieved by anesthetizing the left tonsil and its pillars.

Since it was felt that this condition was probably due to the fact that some of the tract had been left behind, tonsillectomy was performed with subsequent alleviation of the pain.

On August 12, about two months after the removal of the cysts, two distinct, very hard masses were palpated behind the sternomastoid muscle.

A week later there was a sudden reappearance of the pain upon swallowing. This pain was much more severe than it had been previously. The swelling in the left piriform fossa seemed to be larger and redder and the mass in the left posterior triangle of the neck was definitely larger.

A few days later, on August 27, he coughed up a considerable quantity of blood and pus, following which the pain was considerably relieved.

Laryngoscopic examination showed the mass in the left piriform fossa to be smaller, paler, and apparently shriveled.

By October 21, there was evidence of laryngeal obstruction. The patient was referred to Dr. Lerche for tracheotomy. Prior to the tracheotomy, one of the glands was removed from the neck. Microscopic examination showed squamous cell carcinoma.

Laryngoscopic examination on January 20, 1928, showed increase in the size of the mass in the larynx. There were many more glands externally.

The patient died April 21, 1928, fifteen months after the onset of symptoms. No autopsy was obtained.

Examination of the first biopsy and of the two branchial cysts was made by Dr. W. A. O'Brien. He found no evidence of malignancy in either of these specimens.

In spite of the impossibility of autopsy confirmation, it seems reasonably certain that this condition was one of branchiogenic carcinoma on the basis of a branchial cyst of the larynx with metastases to the glands of the neck. This picture was further complicated by the presence of two benign branchial cysts of the neck.

Just when the metastasis to the glands of the neck took place cannot be accurately determined, although it is my belief that it had already taken place when the patient first consulted me and that the second implantations were too small to be seen or were not in the operative field at the time the branchial cysts were removed.

Subsequent to removal of the two branchial cysts, gradually enlarging masses appeared posteriorly to the incision. On account of their location and because of the fact that the branchial cysts showed evidence of marked chronic inflammation with considerable thickening of their walls this enlargement was at first looked upon as inflammatory and its true character overlooked. That these metastases were secondary to the growth in the larynx seems indisputable since there was no other primary focus demonstrable. That the growth in the larynx was branchio-genic in origin seems to be established by the fact that there were other branchiogenic rests present. That it was cystic is proved by its appearance and its subsequent rupture and drainage of cyst contents, and that it was malignant, by its continued growth even after spontaneous drainage of its contents.

DISCUSSION

To show clearly the embryologic significance of the occurrence of two distinct branchial cysts, each of which has a separate tract, one pointing toward the pharynx and the other toward the larynx, is not permitted by the limited time at my disposal, so I shall omit all discussion of this interesting feature and discuss briefly branchiogenic carcinoma of the larynx.

Malignant degeneration of a branchial cyst was first reported by Von Volkman in 1882. McFarland's report in 1926 brought the number of cases to 359. Belk in 1927 reported ten cases. Most figures regarding the number of these cases are undoubtedly too high because of the fact that different authors employ varying criteria in establishing a diagnosis. For instance, by many, mixed tumors of the parotid are included under the head of branchiogenic tumors. Furthermore, many call all malignant tumors of the neck, which have no demonstrable primary focus, branchiogenic tumors.

When we bear in mind that many cases have been called branchiogenic tumors even without postmortem examination to rule out a primary focus, it is apparent that many cases so reported are not branchiogenic carcinoma at all but are secondary to undemonstrated minute primary foci in the nasal sinuses or the larynx. The only lesions whose branchiogenic origin can be established beyond doubt are those which have a cystic structure so that it can be reasonably assumed that the carcinoma began on the basis of a branchial cyst. In solid tumors suspicion always remains that they are secondary and the primary lesion has been overlooked. This fact has been previously stressed by Carp and Stout, by McKenty, Richardson, Brandt and Hudson.

If we include only cases which are undoubtedly malignant degeneration of pre-existing cysts, this condition becomes much rarer than the literature suggests.

One such case has been reported by McKenty. Roeder has reported a case which was operated upon by removal of all the structures from the right side of the neck. This patient was well four and one-half years after the operation.

Schriener reports 16 cases out of 7,376 records since 1914, although whether these are all strictly branchiogenic carcinomata might be reasonably doubted for the reasons stated above.

Carp and Stout, out of 3,961 neoplasms observed at the Presbyterian Hospital and of which 1,538 were cancers, found only four of branchial origin.

According to Ewing, these tumors are of two types —solid and cystic; the usual form being cystic. Ewing further states that definite information in this field is lacking.

The treatment of this type of tumor is most discouraging. Except for Roeder's patient who was apparently well four and one-half years after a very radical operation, all of the cases ended fatally, a few months after recognition. X-ray and radium therapy seem to be of little if any avail.

In the literature, I have not come across a case of branchiogenic carcinoma of the larynx. Even benign branchial cysts of the larynx are extremely rare.

In 1929 Imperatori operated on a branchiogenic cyst of the larynx by thyrotomy, with complete recovery.

In 1928 Watson reported a case in which the cyst encroached upon the glottis and caused sudden suffocation and death. It is of interest to note that in this case the voice, prior to the fatal attack, had never been affected.

Rosenberger reported a cyst in a new-born, causing increasing dyspnea with death from suffocation, after four weeks.

CONCLUSIONS

Early diagnosis of malignancy seems very difficult. Treatment after the malignant stage has been reached seems very ineffective, although the very radical method suggested by Roeder offers some promise. Because of the relative frequency of malignant degeneration it seems justifiable for this reason alone to remove all branchial remnants as soon as they are recognized.

PRESIDENT'S LETTER

THE Seventy-Eighth Annual Meeting of the Minnesota State Medical Association is now history, and, therefore, thanks, appreciations and certain retrospective reflections are in order.

Perhaps the most conspicuous thing revealed by each of these great state gatherings of medical men is the large number of busy, important men who are taking an active part in the routine detail of the affairs of organized medicine in Minnesota.

More than twenty committee reports were received and acted upon in two brief House of Delegates sessions, representing the year-long, hard work of an infinitely greater number of men. I am disposed to challenge any other organization, of whatever kind, in Minnesota to exhibit a comparable interest and willingness to work on the part of its members.

It is worthy of note that the House of Delegates worked efficiently and well, and with extraordinary harmony. These two sessions, with the council meetings that preceded and followed them, constitute an outstanding example of what great bodies of men may accomplish, given willingness to work and the sense and intelligence necessary to participate in the give and take of discussion without acrimonious feeling.

Expressions heard from the floor of the house were unanimous in their appreciation of the year's work of the committees, particularly of the great major committees, the Public Health Education, and that on Public Policy and Legislation. These committees are all engaged in the business of transforming the profession of medicine in Minnesota from a collection of unrelated units to a powerful, responsive and responsible instrument, competent both to assume proper leadership in a public-health-minded world and to protect both itself and the public against irresponsible, socialistic experiments.

The special committee appointed last year to study the policies of the organization made its first report at this meeting. This committee was composed of five busy practitioners, and the report they prepared, which obviously required a great deal of time and careful study in its compilation, was a conscientious, sane, unbiased appraisal of the worth of our activities, with equally sane and well considered recommendations for the future. The report was thoughtfully considered, both by the Council and the House of Delegates, and the discussion which it prompted in both bodies will remain one of the high points of the 1931 meeting. It is by such unprejudiced, impersonal self-estimations that great organizations, as well as individuals, keep their perspective and continue to direct their energies toward wise and essential ends.

A new committee was formed at this meeting, likewise, which is directed at the most vital present problem of medicine. This is the Committee for the Study of the Problem of Medical Economics. No one who attended this meeting, or who picks up any of the better class lay magazines on the news stands can fail to be impressed with the great need for such studies among practical, practising medical men. Curiously enough, it is the sociologist, the social worker, the school man, the public health worker, the employee of the scientific foundation, who has offered most of the testimony hitherto and dug up most of the accepted facts. It is none too soon for the practising physician to make his contribution. Such a study as this committee contemplates is no vague research thrusting at shadowy adversaries. It must be a practical fact-gathering body looking to some immediate practical program for the adjustment of our own economic problems. It deserves the best brains and efforts which our association can muster. It will have a high function to perform in the medical rearrangements of the future, a heavy burden of responsibility for the proper steering of our course out of present economic entanglements. Of that we should all be well aware.

I wish to recall the graceful tribute, with its accompaniment of a gift, which was bestowed upon Dr. Workman, at this meeting, for his years of loyal service and hard work for the association. It was a pleasant incident of the banquet and of the meeting. Dr. Workman has deserved well of our association. He has worked without the slightest thought of a reward and sometimes, no doubt, it has seemed a *thankless* task. He now knows that he always has had the respect, gratitude, and loyalty of his associates.

In closing may I add this bit from Lowell Hoyt? It seems to me a very pertinent quotation.

> "It is spring. Things are looking better. Folks feel better, but a lot of encouragement is needed. Everybody should be a disciple of optimism. Talk it. Act it. It is contagious, makes people forget past failures and the faults of others, and it will inspire them with finer courage, greater enthusiasm and a new hope and new spirit of accomplishment."

L. Sogge

President
Minnesota State Medical Association.

STREPTOCOCCUS VACCINATION IN CHRONIC ARTHRITIS

The classification of arthritis is at present unsatisfactory. While the etiology of certain forms of arthritis is known, there is no agreement as to the cause of acute rheumatic arthritis and chronic arthritis—hypertrophic, atrophic, rheumatoid—call it what you will.

Clinically acute rheumatic arthritis, subacute bacterial endocarditis, and infectious arthritis have been considered separate entities, although confusion in diagnosis occasionally may occur. Pathologically the endocardial lesions in the first two diseases mentioned, while usually easily differentiated, are certainly at times similar and may occur simultaneously. The Streptococcus viridans has been established as the cause of subacute bacterial endocarditis. Clawson's finding of a green-producing streptococcus in an appreciable percentage of cases of acute rheumatic fever has convinced him of the identity of the two diseases. It is rather startling to have him announce that he has identified the same organism from the blood in fifty per cent of chronic arthritis cases, indicating the common etiological factor in the three diseases.

Immunological studies of the blood in acute rheumatic arthritis cases by Birkhaug and Swift, Clawson, and others have shown these patients to be hypersensitive to streptococci. Clawson has shown by experiments on animals that hypersensitiveness to streptococci can be produced by subcutaneous inoculation of streptococci and agar, with the production of an abscess, and further that these animals can be desensitized by intravenous (not subcutaneous) injection of streptococcic vaccine. Extending these observations to clinical application, patients with not only acute rheumatic fever but with chronic arthritis have been and are being treated by intravenous vaccination with a streptococcic vaccine. This is not the first time that vaccine or even streptococcic vaccine has been recommended for chronic arthritis. Typhoid vaccine intravenously in these cases has been tried extensively with but only a modicum of success. Coley's fluid has had some vogue. Clawson's experiments seem to indicate that the desensitizing effect is not due to a foreign protein but can be obtained by various members of the streptococcus family. He is using in his clinical experiments a stock culture of a Streptococcus viridans derived some eight years ago from the blood of a patient suffering from acute rheumatic arthritis.

As a result of the untimely lay publicity regarding the clinical trial of this vaccine in chronic arthritis patients, Dr. Clawson has been swamped with letters from sufferers in every state in the union and physicians have been importuned to get by hook or by crook some of the new vaccine. It is unfortunate. Dr. Clawson himself admits the work is in an experimental stage and has wisely refused to distribute the vaccine widely. Those who heard him speak at the state medical meeting and who heard Dr. Wetherby describe the clinical phase of the work being done, know that conclusions as to the ultimate value of the administration of streptococcic vaccine intravenously in chronic arthritis cannot be drawn. Dr. Clawson is a careful observer and it is certainly to be hoped that his studies will add to our woefully limited means of treatment of this disease.

THE STRANGE CASE OF DIABETES

It is startling to learn that the mortality from diabetes in this country has shown a decided increase in spite of the discovery of insulin. It seems impossible. The discovery of insulin has been rightly hailed as one of the outstanding triumphs of medical science during the past decade, and its use in diabetes has proven invaluable in the prevention of death from coma and in obviating the necessity of markedly restricted diabetic diet. So striking has been its effect that the impression has been given by no less authority than Dr. Joslin that there is no excuse for a diabetic dying from his diabetes. This is doubtless an overstatement of the case. On the other hand, the prevention of many deaths from coma and the prolongation of life in youthful diabetics would naturally increase the percentage of diabetic deaths due to concomitant arterial diseases.

The February 5 number of the *Spectator* contains an article by no less an authority than Frederick L. Hoffman, Consulting Statistician of the Prudential Insurance Company, entitled "The Diabetes Record of 1929," which compares the mortality from diabetes in pre-insulin and post-insulin years. For fifty American cities, the death rate has mounted from 15.9 per 100,000 in 1912 to 23.3 in 1928, declining in 1929 to 22.9. Comparing the mortality rates for the years 1920 and 1927 in the registration area of this country, the reduction in both sexes during the youthful decades has been marked, while in the later decades the increase is startling. It is interesting to note that, while the mortality is slightly greater for the female sex in the first two decades of life, this predominance in the female sex is markedly in excess in the later decades. Comparing the figures for 1920 with those of 1927, this increase in mortality begins to make itself apparent after the age of fifty in males, whereas in females it becomes more apparent at the age of thirty-five. Another striking feature brought out is the marked variation between the mortality from diabetes in different cities, and from year to year in the same city.

What explanation can be given for this disappointing result?

In the first place diabetes is unquestionably more frequently diagnosed than formerly. The much more frequent life insurance and periodic health examinations of recent years have resulted in the detection of many unrecognized cases of diabetes. In former years, the associated existence of diabetes was doubtless often overlooked in patients dying of stroke, heart disease and gangrene.

This, however, does not explain the total increase in diabetic mortality. Certain other facts play a part. In the first place, diabetics are notoriously lax in their adherence to a restricted diet. The expense of daily insulin administration frequently results in its discontinuance. Then again insulin has little effect in the presence of acute infections and the diabetic has a poor resistance to various infections.

In view of the known facts, it seems highly probable that the incidence of diabetes in this country has greatly increased. This view is supported by a comparison of mortality records in this country with those of foreign countries. Compare the figure of 18 per 100,000 in our country at large with that of 11.4 in England and Wales and 6.3 in Italy for the year 1926.

It is not unreasonable to look for some fundamental error in our national diet to account for the picture. The increase in the per capita consumption of sugar in this country from 79 pounds in 1915 to 110 pounds in 1927 is suggestive if our ideas of obesity and overconsumption of carbohydrate as etiological factors in diabetes are correct. Here is a definite opportunity for the medical profession to advise the public of the probable danger that exists in the present day overindulgence in candy and sweets.

UNVERSITY HOSPITAL STAFF REPORTS

The writer has recently had the loan of an unusual document developed intramurally by the University of Minnesota Hospital staff. In addition to a report of the clinico-pathological weekly conference and some snappy news items, the necropsy reports are interspersed with timely comments and deductions. But the most striking feature consists of the unusual abstracts from the literature, usually inspired by the cases under discussion and study.

Students and practitioners have long wanted some reliable, authoritative, easily available statement of current opinion or expression on outspoken clinical entities or syndromes. Text books rarely meet the need because so all-inclusive; much specific information is widely dispersed. A good text is scarcely written before it is incomplete. Then not all doctors have easily available the library and journal facilities found at our universities.

Therefore a set-up of "abstracts" dealing with a subject like "Jaundice" or "Lung Malignancy" has a mine of fresh, vivid and useful information, quickly orienting the reader to permit him to meet patients who have such disorders with greater decision and accuracy. It is to be hoped that in time these reports will expand into a publication for general use and distribution.

E. L. T.

OBITUARY

Dr. O. S. Neseth

1886-1931

Dr. O. S. Neseth of Kenyon died April 23, 1931, following an attack of influenza and pneumonia.

Dr. Neseth was born in Kenyon Township on December 25, 1886. He attended the Red Wing Seminary and obtained his medical degree at Northwestern University.

During the World War Dr. Neseth served as First Lieutenant in the Medical Corps. After practicing a few years in Decatur, Illinois, he moved to Kenyon shortly after the death of Dr. J. A. Gates in the summer of 1923.

Dr. Neseth was Master of the Masonic Lodge at Kenyon at the time of his death and a member of the Odd Fellows Lodge. He was also a member of the Rice County Medical Society, the Minnesota State Medical Association, and the American Medical Association. He was an ardent fisherman and a great devotee of the game of golf.

Dr. Neseth is survived by his wife, Julia; a niece, Mamie Keller; his father and mother, Mr. and Mrs. Sever Neseth; three brothers, Nels, Fred and Carl; and two sisters, Christine and Clara.

Charles Sumner Bigelow

1845-1931

Dr. Charles Sumner Bigelow was born at Middlebury, East Akron, Ohio, December 15, 1845, and died suddenly at his home in Lynwood, California, April 13, 1931, at the age of eighty-five years. He was buried in Roosevelt Cemetery there, April 15.

Dr. Bigelow served in the Civil War in Co. F., 3rd Regiment, Wisconsin Volunteer Infantry. He graduated in Medicine and Surgery at the University of Michigan in 1873. That fall he was married to Miss Abigail Alma Pierce, from which union five children were born. He came to Claremont, Dodge County, Minnesota, in 1881, where he remained for three years. He went to Kansas for the next six years and returned to Dodge County in 1890. He located at Dodge Center, where he practiced until he retired in 1912.

Mrs. Bigelow died in 1910 and Dr. Bigelow was remarried to Miss Neva Bromley of Dodge Center, in 1916. They made their home at Two Harbors, Minnesota, until 1925, when they moved to California.

Dr. Bigelow served the people of Dodge Center for twenty-two years and was well known throughout the country. He was a member of the Masonic Lodge, the Knights of Pythias, Congregational Church and many other local organizations for many years.

Dr. Bigelow was a member of the State Medical Association for many years and was instrumental in organizing the Dodge County Medical Society in 1905.

Besides his many friends, Dr. Bigelow leaves to mourn his passing, his wife, Mrs. Neva Bigelow, two daughters, Mrs. Delia Pierce and Mrs. Chris Darsnek, two sons, Dr. Charles Bigelow and Major Albert S. Bigelow.

PERTUSSIS VACCINES OMITTED FROM N.N.R.

The Council on Pharmacy and Chemistry reports that pertussis bacillus vaccine was admitted to New and Non-official Remedies in 1914 on the basis of what appeared to be acceptable clinical evidence. In subsequent years, when vaccine therapy was at its height, pertussis bacillus vaccine was used extensively and yet critically controlled reports did not become available. In 1928 the Council voted to omit pertussis vaccines with the close of the longest period for which any one was accepted, unless in the meantime acceptable evidence for its usefulness in the prevention or treatment of whooping cough became available. No acceptable confirmatory evidence having become available, the Council voted to confirm its decision to omit from New and Non-official Remedies all pertussis vaccines. (Jour. A. M. A., February 21, 1931, p. 613.)

« A PAGE FORUM OF THE COMMITTEE ON PUBLIC HEALTH EDUCATION »

That the doctor has made great strides ahead in the conception of his duties to the public was demonstrated conspicuously in an obscure breakfast meeting between representatives of the State Medical Association and the Minnesota Editorial Association on Tuesday, May 5. Steadily the obstacles in the minds and traditions of the profession are being removed so that the doctor, and not the free lecturer with an almanac to sell, may be the real teacher of public health and public welfare.

In witness of the new trend, five Minnesota physicians—representatives of the association—and five representatives of the Minnesota Editorial Association inaugurated what is likely to be a new era in Minnesota in the relations between these two groups.

Technically this meeting was designed merely to pave the way for the appointment by both associations of a standing advisory board to be composed of five editors and five physicians with the widest possible representation in the state, whose duty it will be to meet regularly and iron out the little differences and misunderstandings and misconceptions that have kept the two looking at each other suspiciously at arm's length everywhere, and to bring about coöperation to effect acceptable methods of legitimate public health education.

This breakfast episode, almost buried in the avalanche of committee meetings and the scientific program of the May meeting, is likely to have a far reaching effect in Minnesota.

It is one of the proud distinctions of organized medicine in Minnesota that it has made unprecedented advances in the coöperation with and direction of public health agencies in the state.

This meeting has laid the foundation for an equally brilliant, sound, and effective coöperation in another direction. Lack of intelligent understanding of each other's problems has been the cause of bitterness and distrust between both professions immemorially. While such a state of things might, and generally did, formerly exist without seriously interfering with the doctor's or editor's function, it is now a thing of the past.

The business of bringing into being everywhere in the big cities and the small towns a happy relationship between editor and doctor is no stupendous task if the friendliness and moderation and understanding displayed at the preliminary meeting is a reliable sign.

Mr. Lou Benshoof of Detroit Lakes Tribune, Jefferson Jones of the Minneapolis Journal, Mr. Roy Dunlap of the St. Paul Pioneer Press and Dispatch, Mr. A. E. McGowan, executive secretary of the association, were among the representatives of the Minnesota Editorial Association present at the meeting.

The resolution passed at this conference follows:

"Be it resolved that this conference favors the forming of an advisory board of public relations between the Minnesota State Medical Association and the Minnesota Editorial Association of five representatives from each association. It is the sense of this conference that the representatives of the two associations be selected so as to have representation of the state at large."

This resolution was read and passed at the House of Delegates meeting later in the day and was similarly approved by the Editorial Association in session later in the same week.

A meeting late in the summer of the two committees is contemplated though their personnel is not yet complete.

OF GENERAL INTEREST

Dr. M. H. Whalen is practicing in Duluth, with offices at 4701 E. Superior Street.

Dr. C. M. Rudie has moved from Mazeppa to Kenyon, Minnesota.

Dr. W. A. Gleason, who completed his interneship at St. Luke's Hospital in Duluth a year ago, is practicing at Osceola, Wisconsin.

Dr. H. F. Bayard, formerly of the Mayo Clinic, Rochester, Minnesota, has opened offices at 420 Medical Arts Building, Minneapolis, and is specializing in proctology.

Dr. J. V. Carlson, following the completion of his interneship at St. Luke's Hospital, Duluth, a year ago, may be addressed at 2 North Garfield Street, Alhambra, California.

Dr. Oliver Heimdal recently completed his surgical fellowship at the Mayo Clinic, Rochester, and has opened an office at 402 Graham Building, Aurora, Illinois.

Dr. H. Longstreet Taylor, St. Paul, was elected to the Executive Committee of the National Tuberculosis Association at its annual convention held in Syracuse in May.

Physicians are reminded of the necessity of filling out a transfer form with the Collector of Internal Revenue when changing their location in order to maintain their registration under the Harrison Narcotic law.

Dr. W. B. Rydell, after serving his interneship at St. Luke's Hospital in Duluth, has entered practice at Buffalo, Minnesota. Dr. R. A. Trombley is now located at Emmons, Minnesota; Dr. H. H. Green at Austin, and Dr. Karl Emanuel at Iron Mountain, Michigan.

Members of the Women's Auxiliary who are planning to attend the National Auxiliary meeting at Philadelphia may obtain hotel accommodations through Mrs. Frederick S. Baldi, Room 304, Chamber of Commerce Building, 1129 Walnut Street, Philadelphia.

Dr. Franklin R. Wright appeared before the Camp Release District Society in Olivia on April 27. Instead of reading a paper he answered questions for three hours on Venereal and Genito-urinary Diseases. Questions were furnished by members of the Society.

Dr. Harry A. Daniels has recently completed a Fellowship in Internal Medicine at the Mayo Clinic, Rochester. He is limiting his practice to Internal Medicine, in Chicago, and is associated with Drs. Arnold H. Kegel and Frederick W. Schacht. Dr. Daniels was formerly in practice, at Eveleth, Minnesota, from 1922 until 1927.

Members of the Minnesota State Medical Association, especially those who attended the Minneapolis Assembly of the Inter-State Postgraduate Medical Association of North America, will be interested to know that the published Proceedings of that Assembly are now available and may be procured through the office of the Executive Secretary, Dr. Edwin Henes, Jr., 759 North Milwaukee Street, Milwaukee, Wisconsin.

The Medical Alumni Association of the University of Minnesota will erect a suitable monument for the unmarked grave of Dr. Perry H. Millard, the first Dean of the Medical School. Dr. Millard was largely responsible for the organization and early development of the school and was also the author of most of the medical laws by which we are governed. Medical Alumni may send contributions for the fund to Dr. Donald Daniel, Treasurer, at 1453 Medical Arts Building, Minneapolis.

Dr. W. A. Fisher, who is president of the Chicago Eye, Ear, Nose and Throat College, and who is noted for his introduction of the Smith Indian method for cataract extraction, came to Minneapolis May 6 to see Dr. C. N. Spratt's method for the extraction of cataract. A luncheon was given at the Minneapolis Club by Drs. C. N. Spratt and Archa Wilcox, and was attended by thirty of the prominent ophthalmologists. Dr. Samuel Higgins, who read a paper before the Minnesota Academy of Ophthalmology and Otolaryngology, witnessed a demonstration of Dr. Spratt's method of operation later in the week.

Dr. Hyman S. Lippman has been appointed director of the St. Paul Child Guidance Clinic and has taken over the post made vacant by the death of Dr. M. L. Stiffler. Dr. Lippman received his medical degree at the University of Minnesota in 1919 and specialized in pediatrics. He was on the staff of the habit training clinics under the auspices of the Minneapolis Infant Welfare Society from 1923 to 1927 and then spent two years on the staff of the Institute for Child Guidance in New York City. Dr. Lippman comes to St. Paul from Vienna, where he spent eighteen months in the study of adult and child psychology.

Dr. Richard E. Scammon, during the present academic year dean of medical and biological sciences at the University of Chicago, will return to the University of Minnesota next fall to fill the newly created post of dean of medical sciences. Dr. Scammon was professor of anatomy at the University of Minnesota prior to his going to Chicago in the fall of 1930. He has done much research work in comparative embryology and the growth and physical development of children, and is the author of several books on these subjects. In his new position he will be especially charged with the stimulation of research in medical science and related fields that requires the coöperation of the various colleges of the University.

COOK COUNTY HOSPITAL CLINICS

The annual post-graduate summer clinics conducted by Cook County Hospital, Chicago, under the auspices of the Chicago Medical Society, will be held June 22 to July 3. Dr. N. S. Davis, III, Secretary of the Society, reports that the clinics will be organized to give the practicing physicians in attendance practical instruction in the line of medicine and surgery. In fact, the two weeks will cover an intensive post-graduate study of the latest modern medical developments. Cook County Hospital probably offers a better opportunity for such study than any other hospital in the country.

Medical men from all sections of the United States and Canada are expected to attend these clinics which will be held from 8:00 A. M. to 5:00 P. M. each day, and the lectures that will be given three nights each week at eight o'clock. Physicians desiring further information about this post-graduate course should write the Secretary of the Chicago Medical Society, 185 North Wabash Avenue, Chicago.

MISCELLANEOUS

TRAINING FOR MEDICAL RESERVE OFFICERS AT THE MAYO FOUNDATION, ROCHESTER, MINNESOTA, AND WASHINGTON UNIVERSITY SCHOOL OF MEDICINE, ST. LOUIS, MISSOURI

Through the courtesy of the authorities at the Mayo Foundation, Rochester, Minnesota, and the Washington University School of Medicine, St. Louis, Missouri, arrangements have been made whereby there will be given a period of fourteen days inactive duty training for Medical Reserve Officers without expense to the government. The dates of this training are as follows:

Mayo Foundation, Rochester, Minnesota, October 18-November 1.

Washington University School of Medicine, St. Louis, Missouri, November 8-November 22.

These courses present to Medical Reserve Officers a two-fold advantage: (a) Medico-military instruction; (b) Refresher course in professional subjects. The courses are so arranged that a Reserve Officer can devote his morning hours in any of the clinics or other purely medical professional studies he desires. The afternoon and evening hours will be taken up entirely with medico-military subjects. The custom of taking annual study courses has become so general among medical men that argument about its advantage is unnecessary. Furthermore, patriotic motives of a Reserve Officer in the interest of National Defense and his advancement in the military service have created a desire for periodic instruction in Medical Department Reserve matters. These two great medical centers have provided the ways and means whereby the two-fold purpose can be accomplished.

For the past two years inactive duty training to Medical Department Reserve Officers has been given during the fall months at the Mayo Foundation, Rochester, Minnesota, for a period of two weeks. The authorities of the Mayo Foundation provided the facilities, including instructors, offices, class rooms, etc., necessary to carry on the school. All expenses incurred, except the salaries of the members of the Regular Army, were borne by the Foundation. The Washington University School of Medicine has offered the same facilities, including clinical instruction in the various branches of medical practice and the clinical material, laboratories, museums, libraries of the school and lecture rooms without charge. A group of faculty members have volunteered to give instruction and hold clinics during the period of training.

At our first inactive duty training camp at the Mayo Foundation most of the students were Fellows of the Mayo Foundation, or otherwise connected with the Mayo Clinic. A few were physicians from other parts of the Corps Area, who profited by having the mornings free to devote to observation of the work at the Clinic. The attendance at this school for the first year was thirty-three (33). The following fall, 1930, another two weeks period of training was provided, with the same facilities as in the previous year, by the Mayo Foundation. Fifty-one (51) Reserve Officers received instruction during this training period. The school was originally established because of the difficulty in granting leave to the Reserve Officers at the Mayo Clinic for camp training in July because of the fact that this was the rush season at the Clinic. After conducting two of these camps the authorities at the Mayo Clinic summarized the advantages as follows:

a. A Reserve Officer in convenient periods of the year receives stimulating personal instruction along military lines.

b. It provides preparation for taking examination for the next higher grade.

c. It affords a Medical Officer the satisfaction of knowing he is better fitted for his present rank.

d. It provides for the combination of military training with a professional observation course at the medical center.

Great interest was shown in these two courses and many of those who attended emphasized the importance of such a course on account of the dual purpose offered a busy doctor, namely, training for the duties required of a Military surgeon and the opportunity for a refresher course in any specialty of medicine.

All applications for the course of training at the Mayo Foundation should be made to the Director of the Mayo Fundation through the Surgeon, Seventh Corps Area, and applications to take the course at Washington University School of Medicine should be sent to the Dean of Washington University School of Medicine through the Surgeon, Seventh Corps Area.

ADDING INSULT TO INJURY—BRAZEN EFFRONTERY OF THE AMERICAN TOBACCO COMPANY

Has your quiet evening enjoyment of the radio ever been disturbed by the raucous voice of the Lucky Strike announcer, informing the world that "Luckies are kind to the throat"? Has your blood *boiled* because of the heat engendered by his slanderous pronouncement that "20,679 physicians have stated Luckies to be less irritating" to the throat and less likely than other brands of cigarettes to induce coughing? Have your respect for science and love of truth suffered under his deceitful, tricky, distorting use of the language of science to bolster up an alleged scientific treatment of tobacco to improve its quality?

Quite aside from its offensive character, as viewed by physicians, the Lucky Strike advertising matter is about the worst that the American business craze for blatant, impudent, false, not-quite-provable-lying advertisements has yet produced. Let us analyze the speech that is repeatedly broadcast and the wording of ads now appearing in daily papers like the New York Times and magazines like the Forum; publications that ought to be but are not above engaging in the spread of such deceptive and misleading material.

The statement that 20,000 physicians signed cigarette testimonials may be true, though we doubt it. But, if it be true that so large a number of educated men could be induced to "sign a blank check," the fact must not be overlooked that in this instance the signatures were secured by methods which smack of fraud. While we feel ashamed of the fact that so many of our brothers proved themselves "easy suckers," the advertiser who procures testimonials through deceptive procedures has little to be proud of or boast about.

The statement—"It's toasted! Everyone knows that heat purifies and so toasting removes harmful irritants that cause throat irritation and coughing"—is made to appear as evidence of a scientific fact, but is, in reality, nothing but a jumble of words covering three alleged facts which have no true relationship to one another. For instance: "Everyone knows that heat purifies." We might retort that everyone knows also that heat *destroys*. What reason is there to suppose that heating will purify tobacco? We may assume the answer would be that heat is destructive only when applied in an intense form, and that purification attends upon the use of heat in moderate degree. Very good, but if by "purifies" it is meant to imply that microörganisms—disease-producing germs—are destroyed, we respectfully submit that a considerable degree of heat is required for that purpose, repeatedly applied in the case of spore-bearing germs, and that the heat of *toasting is not sufficient* to accomplish the purpose. A very simple experiment can be tried in the kitchen. Would any bacteriologist testify that toasting a slice of bread will destroy pathogenic germs on or in that bread, and thus purify it? We think not. Which disposes of that alleged fact.

Perhaps germs were not meant; we admit they were not mentioned, but we are unable to think of any other form of purification that could have been alluded to in that statement. The second alleged fact (or is it a deduction from the previously alleged fact?) is that "toasting removes harmful irritants." What irritants? Bacterial, as referred to above, or chemical? If the claim refers to chemical substances, pray tell us what chemical irritant can be removed from tobacco by the simple process of "toasting." We have some knowledge of chemistry but need help to solve that problem.

Thirdly, it is stated that toasting removes "irritants that cause throat irritation and coughing." Again, may we ask what is the name and nature of these irritants (characterization of a single one will satisfy our personal curiosity) that irritate the throat and induce coughing? If the claim can be sustained, that smoking tobacco or cigarettes of any kind produces of itself a specific irritation of the throat and a characteristic cough, there are several thousand specialists in affections of the throat who will welcome proof thereof, and who will be particularly glad to be enlightened as to the specific nature of the irritant.

But that is not all—we had almost forgotten the greatest claim of all: "Everyone knows that sunshine mellows—that's why toasting includes the use of the Ultra-violet Ray." Ah! What a lucky strike! Ultra-violet rays (why not vitamins)—fads of the day—must be worked in to aid the old-fashioned toasting. "Sunshine mellows"—perhaps, but who has proved that it is the ultra-violet end of the spectrum that produces the mellowing effect, on fruit for instance, and what constitutes the mellowing of tobacco? Like Hashimura Toga, "We ask to know."

What, then, does our analysis show? In plain English, it shows that the bombastic radio announcement and the printed advertisements referred to are a tissue of falsehoods strung together in such an impressive manner as to deceive the simple-minded listener and reader, and the advertiser doubtless hopes that repetition of deceptive statements will give them the effect of truthfulness. And the medical profession is made to appear as endorsing all this tommy-rot.

What can we do about it? Shall we, 100,000 or more physicians, supinely submit to these nightly radio and daily newspaper insults of the Lucky Strike manufacturers, or shall we make some effort to suppress such advertising and to protect the public and ourselves against misleading, deceptive and slanderous broadcasting, whether by radio or printing?

You may recall that the old slogan of this same company—Reach for a Lucky Instead of a Sweet—was quickly withdrawn when the sugar trust aided the candy-makers in a demand for suppression.

—*Journal of the Medical Society of New Jersey,* February, 1931.

Do not forget the date of the American Medical Association meeting which takes place June 8 to 12, inclusive.

CONSULTATION BUREAU

Wm. A. O'Brien, M.D., *Director*
Minnesota State Medical Association
11 West Summit Avenue
Saint Paul, Minnesota

1. *Question*—About 1927, a young wife came to me complaining of "rheumatic" pains in the back and shoulders. She is very short, fleshy, weighs 165 pounds although only 5 feet 3 inches in height, very athletic, being able, when well, to swim a mile without effort. She has a history of having had "grippe" every year as long as she can remember. She has chronically infected tonsils which are adherent. No other diseases. Father has diabetes in a rather mild form. Mother died of carcinoma of breast. Brother and sister living. One brother died of tumor of pineal gland. The patient had her first baby in January, 1928, and her second in March, 1930. Since 1927 her "rheumatism" has progressed. Tonsils were removed in March, 1927. In 1928 she began to have pains in her knee joints and fingers. The only time she has not been bothered with joint pains was during the last pregnancy. So far the case seems perfectly clear but the peculiar part of it is that she has these pains in periodic attacks beginning regularly every ten days apart, at which time the knee joint swells and fills with fluid. The swelling is so severe that she can not walk except with great difficulty, and then in two or three days the swelling and pain are gone and she can walk as well as ever. There is usually slight tenderness for a day or two following. I have on two occasions drawn out an ounce or more of fluid from the knee joint and tried to grow the organism at the laboratory but without success. The fluid is clear, amber, and contains many leukocytes but we can not find any bacteria. In 1927 or 1928 a consultant saw her and thought she had a streptococcus viridans type of arthritis deformans and gave her large doses of sodium cacodylate intravenously without very much improvement. Salicylates had no effect. In the earlier part of her disease, the leukocyte count was from 12,000 to 20,000. It is never found below 11,000. The information I desire is this: Does a streptococcus type of arthritis cause periodic recurrence of pain without deforming effects? Have you any suggestions as to treatment? I am now using triple typhoid injections, starting with 12½ million and increasing the dose.

   Answer—This type of patient has been recently studied at the University of Minnesota by Drs. Macnider Wetherby and B. J. Clawson. They find in one-half of their cases a positive blood culture of streptococci, usualy streptococcus viridans. After studying this group of patients with pain, tenderness, swelling, and disability of the joints with or without deformity, they came to the conclusion that many of them were atypical variations of the same process. Animals can be immunized against the organism by intravenous injections of streptococcic antigen. This causes the titre to rise without increasing the sensitivity as evidenced by skin tests. On this basis, they have treated a considerable number of patients and note that improvement follows in about 75 per cent. They believe that their treatment is not an atypical foreign protein reaction but think it is a more or less specific response. This type of infection, undoubtedly, has an allergic factor and the periodic symptoms of pain, tenderness, and swelling are in accord with such a belief. At the present time, Drs. Clawson and Wetherby are continuing their studies but are not yet ready to release the antigen for general use. I have asked them to get in touch with you in regard to the matter. It is our impression that your patient has a streptococcus viridans type of arthritis without deformity. Removal of foci of infection may or may not have any influence on the course of the disease as reinfection may take place from foci in the joints. You might continue to use triple typhoid vaccine or boiled milk although this treatment is not uniformly successful.

2. *Question*—When is the best time to operate on a spina bifida?

   Answer—As a rule, if an operation can be done, it should be deferred until the child is able to stand the shock. Operations are usually attempted before the child starts to walk and possible injury results from bumping against things. In the interval, the parents will be able to see that a certain amount of progress (if paralysis is present) is taking place so that the operation is not blamed for any continuation of the process. If you would restate the case, we would perhaps be able to give you more definite information but, as a general rule, operation is deferred until just before the patient begins to get about with a possibility of injury.

3. *Question*—The patient is a single nurse, 21 years of age. She has complained of feeling tired for the past six months, lost eighteen pounds in weight, and runs a temperature of 99.5 to 100.5 but this is inconstant. No cough. She has had frequent colds the last winter with rather severe chest pains. No history of tuberculosis in her immediate family but one grandmother had tuberculosis. On physical examination, the chest does not show anything striking. Urine negative. Appetite good. No night sweats. An X-ray of chest revealed clear apices but moderate thickening of hilus. In addition, there is a slight increase in bronchial markings, especially in the lower lobes. The size of the hilus may be slightly exaggerated because the patient is slightly turned.

   Answer—The absence of parenchymal findings is against the X-ray diagnosis of tuberculosis. In the absence of sputum, it is impossible to rule out tubercle bacilli which would be diagnostic. A positive tuberculin reaction would indicate tuberculous infection but might not have anything to do with the present condition. A negative reac-

REPORTS AND ANNOUNCEMENTS OF SOCIETIES

MEDICAL BROADCAST FOR THE MONTH

The Minnesota State Medical Association Morning Health Service

The Minnesota State Medical Association broadcasts weekly at 11:15 o'clock every Wednesday morning over Station WCCO, Minneapolis and St. Paul (810 kilocycles or 370.2 meters).

Speaker: Dr. William A. O'Brien, M.D., Associate Professor of Pathology and Preventive Medicine, Medical School, University of Minnesota.

The program for the month of June will be as follows:

June 3—Ringworm of Feet.
June 10—Toxemia of Pregnancy.
June 17—Erysipelas.
June 24—X-ray and Radium in Treatment of Cancer.

THE RECENT STATE MEETING

A registration of more than nine hundred physicians, from all over the Northwest, with isolated representations from great distances, marked the successful Seventy-Eighth Annual Meeting of the Minnesota State Medical Association which occupied Tuesday and Wednesday, May 5 and 6, at the Nicollet Hotel in Minneapolis.

A day and a half of lectures at the hotel and a half day of clinics at the University hospitals constituted the scientific program of this meeting with George Gray Ward, Jr., of Cornell University, New York, and Drew Luten of Washington University, St. Louis, Mo., among the distinguished visiting speakers.

Officers elected at this meeting, to take office in January, 1932, were: M. S. Henderson, Rochester, president; B. S. Adams, Hibbing, first vice president; A. E. Hedback, Minneapolis, second vice president; E. A. Meyerding, St. Paul, secretary, and W. H. Condit, Minneapolis, treasurer. Herbert Giffen, Rochester, was elected councilor to succeed Dr. Henderson. Other councilors re-elected at the expiration of their three year terms included: H. M. Workman, Tracy; F. J. Savage, Saint Paul, and W. W. Will, Bertha.

One of the outstanding undertakings of the House of Delegates was the consideration of the report of the committee appointed last year to study the future policies of the Association. This committee presented its report for discussion before the Council, and both sessions of the House of Delegates, through its chairman, O. E. Locken, and was accepted with some additions and changes by that body.

Formation of another new committee to be called a Committee to Study the Problem of Medical Economics also marked the House of Delegates meeting at its final Wednesday session. In all, more than twenty committee reports were received and passed upon by the body.

The presentation of a watch to Dr. H. M. Workman, Tracy, in recognition of long and faithful service as president of the Council, was a surprise feature of the banquet on Tuesday evening. A crowd that seriously taxed the capacity of the hotel to accommodate it, attended. C. H. Mayo, Rochester, acted as toastmaster, the banquet program including, besides the presentation address of A. S. Hamilton, Minneapolis, the presidential address of L. Sogge, Windom, a talk by Mrs. James Blake, Hopkins, president of the Women's Auxiliary to the Minnesota State Medical Association, and Congressman W. I. Nolan of Minneapolis on "My Friend the Doctor."

St. Paul was selected as the place of the next meeting, the date to be decided later by the Council.

AMERICAN PROCTOLOGIC SOCIETY

The thirty-second annual meeting of the American Proctologic Society will be held in Philadelphia, Sunday, Monday, and Tuesday, June 7, 8, and 9, 1931. The scientific sessions will be on June 7 and 8, and all members of state medical societies are cordially invited to attend.

PAN AMERICAN MEDICAL ASSOCIATION

The third congress of the Pan American Medical Association will be held in Mexico City, July 26-31, 1931, under the auspices of the government of the Republic of Mexico.

The purpose of the Association is to promote a more intimate understanding between the medical men of North and South America. An effort is being made to further medical contacts between English, Spanish, French and Portuguese speaking physicians of Pan America, and a cordial invitation is extended to all physicians interested.

This meeting affords an opportunity for physicians in this country to pay a visit to our sister republic; a trip which has become more and more popular in the last few years.

Further information may be obtained by addressing Dr. Francisco de P. Miranda, Executive Secretary of the Organization Committee, Departmento de Salubridad Publica, Mexico City, Mexico.

STEARNS-BENTON COUNTY SOCIETY

The annual meeting of the Stearns-Benton County Medical Society was held April 25, 1931, at the U. S. Veterans Hospital, St. Cloud. The Society was entertained at supper as guests of the hospital staff.

The following officers were elected to serve until January, 1933, since it was the sense of the meeting to amend the Constitution to end the fiscal year in December rather than in April as at present: Dr. William Friesleben, Sauk Rapids, president; Dr. Julian F. Du Bois, Sauk Centre, vice president; Dr. Wm. H. Rumpf, Jr., Saint Cloud, secretary; Dr. Francis J. Schatz, Saint Cloud, treasurer.

Censors: Dr. George E. Sherwood, Kimball, three years; Dr. Richard N. Jones, St. Cloud, two years; Dr. William L. Freeman, St. Cloud, one year.

Delegate: Dr. John P. McDowell; alternate, Dr. John N. Libert.

Dr. R. H. Sweetman of Sauk Centre was unanimously elected an honorary member of the Society, having completed the requirements.

William H. Rumpf, Secretary.

MINNESOTA RADIOLOGICAL SOCIETY

The annual meeting of the Minnesota Radiological Society was held in Minneapolis May 4, 1931. The following program was presented:

ROUND TABLE DISCUSSIONS

1. Therapeutic X-ray Dosage and Measurement Problems. Conducted by
   Dr. E. T. Leddy, Rochester.
2. Gastric Ulcer
   Conducted by
   Dr. J. Richards Aurelius, St. Paul.
3. Traumatic Spine Lesions
   Conducted by
   Dr. Gage Clement, Duluth.
4. The Chest in Children
   Conducted by
   Dr. Malcolm B. Hanson, Minneapolis.

INFORMAL DINNER

Address: The Intervertebral Disc. Dr. Emil S. Geist, Minneapolis.

Pathologic and Roentgenologic Study of Joint Diseases, Dr. R. K. Ghormley, Rochester.

The present officers were re-elected for the coming year as follows:

Dr. B. R. Kirklin, Rochester, president; Dr. Gage Clement, Duluth, vice president; Dr. Leo G. Rigler, Minneapolis, secretary-treasurer.

Leo G. Rigler, M.D., *Secretary-Treasurer.*

RED RIVER VALLEY SOCIETY

The Spring meeting of the Red River Valley Medical Society was held in Crookston, Minnesota, April 14, 1931. The following program was presented:

1. Diathermy in Acute Pulmonary Diseases.
   Dr. G. S. Wattam, Warren, Minnesota.
2. The Office Treatment of Diseases of the Cervix, with Special Reference to the Cautery.
   Dr. J. R. Manley, Duluth, Minnesota.
3. Advances in the Diagnosis of Heart Disease.
   Dr. O. E. Locken, Crookston, Minn.

C. L. Oppegaard, *Secretary-Treasurer.*

UPPER MISSISSIPPI MEDICAL SOCIETY

A meeting of the Upper Mississippi Medical Society was held at Wadena, April 25, 1931. Papers were given by John F. Madden, of St. Paul, on "Diagnosis and Treatment of Common Skin Diseases," and by W. Ray Shannon, of St. Paul, on "Infantile Tetany."

F. W. Van Valkenburg, *Secretary.*

INTER-STATE POST GRADUATE MEDICAL ASSOCIATION OF NORTH AMERICA

The next annual meeting of the Inter-State Post Graduate Medical Association will be held at Milwaukee, October 19 to 23, 1931.

The names of those who will take part in the scientific program have been announced and the coming meeting promises to be as comprehensive as the recent meetings have been.

For further information, the secretary, Dr. Edwin Henes, Jr., Milwaukee, may be addressed.

WOMEN'S AUXILIARY
Minnesota State Medical Association

President—Mrs. S. S. Hesselgrave, St. Paul
Chairman Press and Publicity—Mrs. E. A. Meyerding, St. Paul
Editor—Mrs. A. A. Passer, Olivia

A meeting of the State Executive Board of the Women's Auxiliary was held at the Nicollet Hotel, Minneapolis, Tuesday, May 5, following a luncheon in the main dining room. Dr. Kathleen Jordan of Granite Falls spoke on "Tuberculosis in Children—the Value of the Mantoux Test."

The annual business meeting of the Women's Auxiliary was conducted in the Hennepin County Medical Society Rooms of the Medical Arts Building, Wednesday, May 6, at 10:00 a. m. Dr. L. Sogge of Windom addressed the assembly. Other speakers included: Dr. W. A. Coventry of Duluth on "The Doctor Looks at the Auxiliary"; Dr. C. E. Rudolph of Minneapolis on "The Cost of Medical Care." Annual reports were given by officers, committees, and county auxiliary presidents.

Mrs. Edward Schons, St. Paul, was elected president of the Women's Auxiliary for 1932. Mrs. James Blake, Hopkins, who was elected last year, will serve as president this year. Other officers elected were: Mrs. R. N. Jones, St. Cloud, first vice president; Mrs. H. M. Blegen, Warren, second vice president; Mrs. J. W. Stuhr, Stillwater, third vice president; Mrs. E. M. Hammes, St. Paul, secretary; Mrs. W. A. Coventry, Duluth, treasurer; and Mrs. M. L. Mayland, Faribault, auditor. Article 3, Section 3, of the By-Laws, was amended to read: "Terms of office shall begin following the National Convention of the Women's Auxiliary to the American Medical Association."

Mrs. S. S. Hesselgrave will attend the National Convention of the A. M. A. Auxiliary as state president, and Mrs. James Blake will attend as a national officer, being second vice president of the Women's Auxiliary to the A. M. A. Minnesota is entitled to nine delegates to the national convention.

Mrs. Martin Nordland, Robbinsdale, was appointed treasurer during the absence of Mrs. W. A. Coventry, who will tour Europe during the summer.

The reports of committees were interesting and showed the great interest throughout the state in the various social, philanthropic and educational activities sponsored by the auxiliary and approved by the doctors.

The luncheon on Wednesday, May 6, was served at the Woman's Club of Minneapolis. Mrs. Martin Nordland, president of the Hennepin County Auxiliary, presided. Speakers included Dr. William A. O'Brien and Mr. H. A. Bellows. A musical program was given by the Thursday Musical Ensemble, under the direction of Mrs. C. Jay Willcox.

The Women's Auxiliary coöperated with the Minnesota Public Health Association in the High School radio broadcasts by offering a Silver Cup for the best radio talk. The cup was awarded to Eugene Lambert of Cloquet and honorable mention to Arnold Lawson of Owatonna, by Mrs. Hesselgrave, state president.

The annual banquet of the State Medical Association and Women's Auxiliary was held at the Nicollet Hotel, Minneapolis, Tuesday evening, May 5. Dr. Charles H. Mayo of Rochester was toastmaster. The address of welcome was given by Dr. S. H. Baxter, president of the Hennepin County Medical Society. Speakers included Dr. L. Sogge, president of the State Association, Mrs. James Blake, president-elect of the Women's Auxiliary, Dr. A. S. Hamilton of Minneapolis, and the Honorable W. I. Nolan of Minneapolis.

May 6, 1931

PRESIDENT'S REPORT

Ninth Annual Meeting—Women's Auxiliary to the Minnesota State Medical Association

Our brief year has come to a close and the report of our activities will soon be filed away with the record of other years. It has been a privilege to serve as president of the State Auxiliary because of the loyal support given me by the Executive Board in carrying out our program and I most sincerely thank the officers, the Committees and the County Auxiliary presidents for their kind and courteous coöperation.

The following have fully earned and receive our highest commendation:

The Organization Chairman, Mrs. James Blake, who has sown seed for new auxiliaries in every corner of the State, of which the harvest of new members has been bountiful. We take the greatest pleasure in welcoming these 210 new members of our State Auxiliary and in wishing them success in their work and happiness in the new friendships to be formed.

Mrs. Hugh Tunstead and her Legislative Committee for the discretion and vigilance exercised during the past legislature.

Our Public Relations Chairman, Mrs. Davis, for a tentative program that our advisors have prepared for auxiliaries who wish to study the most recent developments in medicine.

Our Press and Publicity Committee in the capable hands of Mrs. E. A. Meyerding, with the valued coöperation of the office of the Minnesota State Medical Association in this field.

Mrs. A. A. Passer, our Editor, who has filled many columns with colorful Auxiliary news. MINNESOTA MEDICINE for the valuable space given, and its Editor, Dr. Carl Drake, for his editorial "The Women's Auxiliary," published in the December number, which has been copied by eastern journals.

Mrs. Carl Larsen, Finance and Budget Chairman, Mrs. Murdoch, *Hygeia* Chairman, Mrs. C. C. Chatterton and Mrs. Peterson, Hospitality Chairmen, and their committees.

Our parliamentarian, Mrs. W. J. Byrnes, who for a number of years has held before us the "Rules of Order," has kept a gracious if rigid count of our parliamentary errors. We respect her opinions, adhere to her decisions and we appreciate her devotion.

Our advisors, Drs. E. A. Meyerding, C. B. Wright, and George Earl, who have kept our course free from entanglements. We urge all county auxiliaries to request the appointment of advisors from their Medical Society. Drs. Sogge and Meyerding for addressing our meetings, and Drs. Critchfield and Hensel for their radio talks.

Our secretaries, Mrs. Boleyn and Mrs. Schons, and our treasurer, Mrs. Coventry, and the auditor, Mrs. Catlin, all deserve unstinted paise.

In November, I had the pleasure of attending the National Executive Board meeting in Chicago, where I met the national officers and presidents of other states. From this meeting I brought back a national viewpoint in Auxiliary work and added enthusiasm for the Women's Auxiliary.

In February I gave a brief talk on "Uses of the Auxiliary" at a Symposium on Public Relations; in March a five minute talk during a Health Radio broadcast over WCCO during Federation hour.

I have been the guest of the following County Auxiliaries: Washington, Wright, Rice, St. Louis, Hennepin and Ramsey. I thank them for their kind hospitality and assure them that I enjoyed their meetings, their reports and their social activities and their courtesy in inviting me.

It was my good fortune to be called upon to coöperate with the Organization Committee in the forming of new auxiliaries, and through the kindness of Mrs. Schons and Mrs. Hewson, who offered their cars, we travelled many hundreds of miles on our quest for new groups during our intensive campaign. We thank Mrs. Braasch of Rochester and Mrs. Lommen of Austin for their kindness to us during our visit in their homes.

I sent out many form letters and wrote hundreds of personal letters that have brought the county auxiliaries in closer contact with the state and national organizations. Our revised Constitution has been printed and distributed. The Treasurer's files have been completed and the Treasurer's receipt forms have been used by all the local treasurers. We thank these patient workers and our Treasurer for her efficient handling of this innovation that has been a revelation as to accuracy of record.

I am sure that the entire State Auxiliary wishes to join me in conveying our sincerest thanks to the capable committees who have worked to make our present stay in Minneapolis so pleasant, and to present our homage to the distinguished president of the Hennepin County Auxiliary and to her entire Auxiliary we say, "Well done, dear friends and neighbors."

In parting I would offer the following recommendations: Have advisors appointed from your Medical Society. Notify the president of a change in officers immediately after their election to office. Collect your dues by January first each year. Adopt a program of activities that help the doctor. Exercise eternal vigilance over the health programs offered by your women's organizations. Do not neglect the social side—it is most important that pleasant relations be established among doctors' wives. Give your new officers the staunch support you have given me.

This is the end of a happy year. To all my coworkers I bid not "adieu" but "Au revoir," and again I thank you.

Respectfully submitted,
(Mrs. S. S.) Marie E. Hesselgrave, *President*

PARK REGION AUXILIARY

The Women's Auxiliary met at the home of Mrs. W. W. Drought of Fergus Falls, Wednesday, April 8. At the business session it was suggested that the Auxiliary obtain a speaker from the State Medical Society to speak to the public, in May. A committee was appointed to arrange for the midsummer meeting.

RICE COUNTY AUXILIARY

A meeting of the Rice County Women's Auxiliary was held in Northfield, April 16, at the home of Mrs. Neil S. Dungay, with Mrs. Orin P. Thorson as assisting hostess. A short business meeting was held and the remainder of the afternoon was spent in sewing for the Red Cross. Refreshments were served at four-thirty, followed by a social half hour.

RESEARCH FOR A NON-HABIT-FORMING SUBSTITUTE FOR MORPHINE

The Committee on Drug Addiction of the National Research Council announces a large collaborative research in alkaloidal chemistry by chemists and pharmacologists of this country. Apparently the present object of the Committee is to prepare a non-habit-forming substitute for morphine that will yet possess the desirable action of morphine. (Jour. A. M. A., March 14, 1931, p. 863.)

CONSULTATION BUREAU

(Continued from Page 566)

tion would aid more in the diagnosis but would not be absolute. Physicians who limit their work to diseases of the chest find cases of this sort rather common. The differential diagnosis is between a non-tuberculous respiratory infection and tuberculosis. Information available to date would seem to indicate the possibility of the former but does not absolutely rule out the latter. She should be watched from this standpoint and other sources of weight, loss, fever, and fatigue kept in mind.

PROCEEDINGS OF THE MINNESOTA ACADEMY OF MEDICINE

Meeting of April 8, 1931

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, April 8, 1931. Dinner was served at 7 P. M. and the meeting was called to order at 8 P. M. by the President, Dr. J. S. Gilfillan. There were forty-seven members and two visitors present.

Minutes of the March meeting were read and approved.

Dr. A. S. Hamilton read the following Memorial to Dr. W. A. Jones:

Dr. William A. Jones died at the Northwestern Hospital January 15, 1931, at the age of 71 years, of which forty-eight were spent in Minneapolis. He was a very active man and in the course of his long life had an important part in many activities. In addition to his private practice, he was for many years a teacher in the School of Medicine at the University; he was on the staff of various hospitals, including a heavy service at the Minneapolis City Hospital for years; he was for thirty years editor of the *Journal-Lancet,* and an active member of the State Board of Health for twelve years. In addition to these, he had time to cultivate an extensive acquaintance among medical men, to give many public addresses and to write many articles. If, as Osler put it, the principal centers of a medical life in a city are the medical school, the hospital, the medical library, the medical society and the medical journal, then Dr. Jones was certainly prominent in every field of medical activity.

His parents were of Scotch and Welsh ancestry. Both his paternal and maternal grandfathers served in the Revolutionary War. His father came to St. Peter in 1854 and his mother in 1858 and both suffered the privations of pioneer life and the horrors of the Indian outbreak of 1862. Dr. Jones was born in 1859.

He attended grade school and high school in St. Peter and when only fourteen years old entered his father's drug store as a clerk and there gained a thorough and practical knowledge of drugs. He later studied medicine at the University of the City of New York and was graduated in 1881 and directly afterward became assistant physician at the State Hospital for the Insane at St. Peter. In 1883 he came to Minneapolis and practised general medicine until 1886, when, after his marriage to Annie R. Johnson of Denver, he went to Europe and took special work in nervous and mental diseases at Berlin and Vienna. On his return to Minneapolis, he began special practice and soon attained a prominent position in the field of nervous and mental diseases, which he retained to his death.

In his lifetime he held many prominent positions, both local and national. At different periods, he served on the staff of the Northwestern, the Minneapolis City, the Asbury, the St. Mary's, the Swedish and the Norwegian Hospitals. In 1913, he founded the South Side

Sanitarium and maintained it as a private hospital almost to the time of his death.

He was a member of the Hennepin County and the Minnesota State Medical Societies and of the Minnesota Academy of Medicine, and had been president of all three. He was also a member of the American Psychiatric Association, and of the American Neurological Society, and was a charter member of the Central Neuropsychiatric Association and of the Minnesota Neurological Society and was president of the latter. He was an active member of the American Medical Association, was Chief of the Section of Nervous and Mental Diseases in 1914, and in 1928-29 served as Vice-president of the Association.

By the very nature of his calling, a physician is more or less a public character. Throughout his professional life, Dr. Jones was deeply interested in the preservation of health and the prevention of disease. On January 1, 1906, he was appointed a member of the State Board of Health and served as such to December 31, 1918, being president from January 10, 1911, to December 31, 1918. During his term of service in the course of some tempestuous activities, he was a loyal supporter of Dr. Bracken as secretary, and particularly so during certain difficulties which arose in the legislative session of 1917 and which resulted in failure to reappoint Dr. Jones. The character of his work on the Board is indicated by the statement of one of its officials that he was a masterful chairman, and, with his sense of humor, his absolutely frank attitude toward all questions and his prompt action, he was the most accomplished and the most efficient member the Board ever had.

In 1890 he was appointed by Governor Nelson a member of the Board of Trustees of the State Hospitals for the Insane and held this position until 1894.

He was Editor of the *Northwestern Lancet* and of the *Journal-Lancet* from 1901 to 1931 and no one who knew him well could doubt his deep interest in and genuine affection for this publication. The Journal catered to the special medical activities and interests of a limited geographic area and Dr. Jones' editorials were its most striking feature. Many medical men have been heard to say that they subscribed to the *Journal-Lancet* for W. A.'s editorials. To most men, the preparation of a series of editorials every two weeks would be a real task. To Dr. Jones it was a labor of love, quickly performed. Without a note at his command, the editorial was dictated as the ideas flowed from his mind and if it had any further corrections they were made at the hands of the stenographer or the publisher. That he had the confidence of the medical profession in his undertaking is shown by the following list of contributors to the first number: Drs. Frank Allport, James H. Dunn, James E. Moore, H. L. Staples, R. O. Beard, and A. T. Mann.

As a clinical teacher of neurology and psychiatry he was always a favorite among the students and out of a very ordinary patient he could always make an interesting case. Though never a profound clinical investigator, he could quickly see the outstanding clinical features of his case, and his diagnosis, whether in the clinic or in private practice, though often of the snapshot type, was generally correct. In 1889 he was made instructor in Nervous and Mental Diseases at the Medical School of the University, became professor in 1900 and served as such to his retirement in 1919. During the Great War he again took up the duties of a teacher in the Medical School in the absence of the regular staff, and also served as a member of a medical advisory board during the war.

Dr. Jones had a large collection of books, both general and medical, and in the later years of his life in particular, when he was often confined to his room for short periods, the writer always found him with stacks of books about his bed. Throughout his life reading was his greatest hobby. His medical library he left to the Hennepin County Medical Society, to which he had contributed liberally throughout his life.

As a practitioner in functional nervous and mental diseases, Dr. Jones was more than ordinarily successful. Possessed of a dominating personality, he impressed his ideas on patients to a very unusual degree and with his characetristic optimism and abounding vitality he inspired them with new hope and courage. Though brusque at times and very blunt, he was always forceful in his relations with patients who accepted his advice and followed his directions as best they could.

Always very fond of music, for many years he had in his own home a pipe organ which he played with much pleasure and he used to tell how he contributed to his scant income, in the early period of his profession, through his musical ability.

All his life he was a hard worker and he had few vacations—the last in 1921—and such as he had were purely urban. He cared nothing for fishing, hunting, or motoring, and his ideal vaaction consisted in a trip to New York, where he spent his days on the top story of a hotel reading and his evenings at the theater. He had a high intelligence and a ready wit and repartee, and was always popular at medical meetings, where he often presided, easily and ably. To the very last he carried with him his unquenchable courage and cheerfulness and his refusal to accept the rôle of an invalid.

He is survived by his wife and a sister, Mrs. J. W. Bell.

Signed: Arthur S. Hamilton,
H. B. Sweetser,
E. M. Hammes,
Committee.

The scientific program was as follows:

Dr. E. M. Hammes (St. Paul) reported a case of Progressive Muscular Atrophy with Initial Involvement of the Upper Spinous Muscles gradually extending to the Scapulo-Humeral Group, with Respiratory Phenomena. The patient was presented.

The patient was a male, 59 years of age, married, a resident of St. Paul. His family history is negative. His personal history shows that he had dropsy in 1893 and an appendectomy thirty years ago. He neither smokes nor drinks. His wife and two children are living and well. She has had no miscarriages.

He stated that for many years his throat has been unduly sensitive to dust and irritating substances. A year ago he had an attack of bronchitis which was relieved somewhat by steam inhalations. Since that time he has had an occasional feeling of tightness in his throat but no obstruction. He paid very little attention to this because it occurred seldom and lasted only a few minutes at a time.

On February 26, 1931, he had a double herniotomy under spinal anesthesia. He did not notice anything until about four days afterward, when he began to have trouble in breathing. There was a great deal of inspiratory weakness but no obstruction. He stated that it felt as if his chest were one great big empty space and that he could not fill it with air. There was no change in his voice, and swallowing was normal.

The inspiratory difficulty has become more constant of late. At first it was intermittent and worse at night. Now it is almost constant and least noticeable when he is lying on his back. When he gets up in the morning and bends over it is most troublesome.

His general physical condition is somewhat below normal. His weight is less than it was a year ago by about 8 pounds. His appetite is fair, his bowels regular, and he sleeps well. He has had arthritic pains in his shoulders and hips for the past few years.

X-rays of his chest show that the diaphragm extends high up bilaterally. His arms feel weak, especially in the shoulders. This has been present for the past year. He has had a feeling of weakness and soreness in both gluteal muscles for the past nine months. In the past two years he has developed some scoliosis and his shoulder blades stick out more than formerly.

The physical examination shows that he has many teeth missing and there is slight evidence of pyorrhea. There is fairly marked winging of the scapulæ.

The neurological examination shows that the pupils, cranial nerves, and fundi are normal. The upper extremities show bilateral atrophy of the shoulder girdle, upper arm, chest and spinous muscles, especially in the upper dorsal region. There is marked coarse fibrillary and fascicular tremors over all these muscles and some slight fibrillary tremors of the gluteal muscles. The muscle strength is impaired and expansion of the chest is limited. The deep reflexes in both upper extremities are present but somewhat reduced. Both lower extremities show normal knee and ankle jerks. There is no ankle clonus or Babinski, and no evidence of atrophy. The muscles in the gluteal region seem to have a little less pronounced tone than those of the other lower musculature. The abdominal and cremasteric reflexes are normal. Sensation is normal throughout. He has quite a marked kypho-scoliosis. The Romberg is negative.

His hemoglobin is 85 per cent; blood pressure 148 systolic, 96 diastolic. Urine is normal.

Dr. Horace Newhart (Minneapolis) read his Inaugural Thesis entitled, "Recent Advances in Deafness Prevention," and demonstrated the use of the audiometer.

Dr. W. F. Braasch (Rochester) read a paper, and showed numerous X-ray films, on "Intravenous Urography."

DISCUSSION

Dr. E. L. Gardner (Minneapolis): What precautions, if any, do you take against reaction in this procedure?

Dr. Braasch: I have never seen any systemic reaction in any of these patients when using skiodan.

Dr. Gilbert Thomas (Minneapolis) (by invitation): I wish to thank the president for the privilege of listening to Dr. Braasch's paper as a guest of Dr. Foley and the Academy of Medicine.

In discussing Dr. Braasch's paper and the conclusions which he has drawn, one must remember he has had a wide experience, and has examined thousands of pyelograms. I was a student with him when he was compiling data for his book on urography, and I know the immense amount of material he reviewed before publishing the book. The same has been true in his experience with skiodan and intravenous urography.

As Dr. Braasch has told you, obstructions in the ureter or any condition which prevents the normal outflow of urine from the kidneys and through the ureters will make a very good urogram after intravenous injection of skiodan. Intravenous urography will orient shadows supposed to be stones in the urinary tract. The size and position of the kidney, together with the identification of masses in the abdomen in relation to the kidney, may be made with skiodan, or intravenous urography.

This drug, which contains a large amount of iodin, is contraindicated when the combined renal function is low. Definite harm may occur in the presence of marked renal insufficiency if it is used.

The technic of intravenous injection should be carefully learned by any one who proposes to use intravenous urography. Much harm and discomfort to the patient may occur if care is not used in the preparation of the water and the solution which is finally introduced into the vein.

When iodin-containing drugs were first used we believed they were contraindicated in the study of tuberculosis of the kidney. However, after chemical analyses by the Mayo Foundation, we learned that Skiodan is eliminated in just the same form as it is given, so that no free iodin is found in the blood stream.

Intravenous urography is particularly helpful when it is impossible to introduce a cystoscope into the bladder. Sometimes this occurs in children. In severe cystitis, particularly tuberculosis, this method of examination is useful, as well as in traumatic conditions of the ureter or bladder. Many times intravenous urography is the only method which can be used for making diagnoses in the types of cases just mentioned.

Intravenous urography, then, is just another method of accurate diagnosis, and should be used as such. I think this point should be emphasized so that physicians and surgeons who have not heretofore interpreted urograms and who have not taken careful histories and obtained other data that is necessary should not use the intravenous urogram as the only criterion for making positive diagnoses.

Dr. S. M. White (Minneapolis): I would like to ask Dr. Braasch how long before the uroselectan or skiodan is given do you cease giving water; in other words, how many hours before the intravenous injection is water interdicted?

Dr. S. E. Sweitzer (Minneapolis): I would like to ask Dr. Braasch if he has seen any cutaneous eruptions from the use of this iodin preparation. Practically every drug that has been administered will occasionally give an eruption on the skin. I have seen some articles that stated uroselectan had caused some skin eruption.

Dr. F. E. B. Foley (St. Paul): Dr. Braasch's opinion and appraisal of this new method are extremely valuable. Most of us have had insufficient experience with it to permit forming so valuable an opinion.

I was gratified to find him so guarded in praising intravenous urography. When I first read Swick's paper, I thought I would have to give up urology in favor of something else, for it appeared that intravenous urography was going to eliminate the cystoscopist. Experience has not borne this out. Those of us who are using it regularly are becoming more and more aware of its limitations. It appears now that the most significant accomplishment of intravenous urography is going to be the easy fereting out of a greater number of obscure urologic conditions that will then be submitted to the more comprehensive study possible by cystoscopy, and the more accurate interpretation permitted by a direct pyelogram.

I endorse enthusiastically all of what Dr. Braasch said, with one exception. Unless I misunderstood him, it was said that in the case of an obscure abdominal condition intravenous urography may be used to exclude the upper urinary tract as a cause. That has not been my experience. I would say that positive findings by intravenous urography may be of extreme value in showing the kidney or ureter to be the cause, but negative findings cannot be relied upon. With the rather poor pyelograms so obtained, it is not possible, for example, to exclude kidney tumor, renal tuberculosis, or slight obstructions.

Dr. Braasch brought out a point which I would like to emphasize. By comparison with direct pyeloureterograms, these are poor pictures in point of interpretive value. He showed from the same case both an intravenous pyelogram and one made by the direct method. It was very obvious, when viewed together, that the intravenous pyelogram suffered tremendously by comparison. When it comes to refinements of interpretation, the very best pyelogram we can get is none too good. Intravenous pyelograms usually fail to show the deformities of early neoplasm, early tuberculosis, small cysts, slight obstructions and changes in the ureter. Accordingly, the negative findings from them have little value.

When it comes to grosser things, such as localization of stone and recognition of obstructions causing well-marked dilatation, the method is of considerable value. With the exception of these two conditions its value is extremely limited in the general run of upper urinary tract conditions.

Dr. Braasch covered the whole field so thoroughly that it is difficult to discuss the subject without repeating the things he has already said. However, there is one more point I would like to repeat and enlarge upon. A use of intravenous urography which appeals very strongly to me is its employment in cases of bladder-neck obstruction. The information we get from phthalein tests and blood chemistry determinations tells us the functional power of the kidney at that particular time. A low phthalein excretion and nitrogen retention may be due either to mere temporary functional block or to extensive and permanent anatomic change. By phthalein tests and blood chemistry determinations we learn nothing of the obstruction and dilatation of pelves and ureters that occur with long-standing vesical neck obstruction. These changes are particularly well disclosed by intravenous urography. Accordingly the method permits us to more accurately appraise the surgical risk, to know the ability to recover function and to judge in advance how long a period of drainage will be required to attain the maximal degree of functional improvement before the operation is undertaken.

Dr. Braasch (in closing): In preparing the patient we simply request that as little fluid as possible be taken for twelve hours prior to urography.

When we used a fifteen per cent solution of sodium iodide for intravenous urography we observed a number of patients with severe skin eruptions caused by iodine absorption. Since using iodine organically combined, as in uroselectan and skiodan, I have not observed any skin reaction.

Dr. Thomas is quite right in statements regarding the difficulties of technic involved. The question may well be asked, who is best equipped to make the intravenous urogram? At the meeting of the American Roentgen Ray Society, which I attended last fall, it was very interesting to find that there were a number of roentgenologists who announced that they were equipped to do intravenous urography. There should be no competition between the roentgenologist and the urologist; they should combine their resources. This is also true of the urologist and the general practitioner. The technical difficulties in the hands of a man accustomed to intravenous manipulation are not many. The greatest difficulty may be found in interpretation.

Although intravenous urography may be of much value in general diagnosis in many ways, it will be of greatest use in that it offers a simple method of recognizing hydronephrosis, which is so frequently overlooked. It will also be of great assistance in the recognition of stone in the kidney and ureter. I do not use the cystoscope now in many of these cases, for, with the evidence that the intravenous urogram offers, there is no object in cystoscopy. It will be a valuable factor in preventing the general man from overlooking lesions of the urinary tract in differential diagnosis.

The meeting adjourned.

R. T. LaVake, M.D., *Secretary.*

PROCEEDINGS OF THE MINNEAPOLIS SURGICAL SOCIETY

Meeting of April 2, 1931

The regular monthly meeting of the Minneapolis Surgical Society was held at the University Hospital on the evening of April 2, 1931. The members of the Society were guests of the Superintendent and Surgical Staff of the Hospital at a 6:30 dinner in the Nurses' Dining Room, after which they adjourned to the Todd Ampitheater for the scientific program, which was a clinical meeting presented by various members of the Surgical Staff. Dr. O. H. Wangensteen, Chief of the Department of Surgery, presided. There were thirty-one members of the Surgical Society present.

The Scientific Program was as follows:

Dr. H. P. Ritchie (St. Paul) said that Dr. Waldron and he had been trying to develop a clinic on plastic surgery to deal with the reconstruction of the various congenital deformities and those that had resulted from traumatism from various causes. A great part of the work still deals with the deformities of the face, generally called "harelip and cleft palate." The first question usually asked is the cause of these deformities. Dr. Ritchie said that they are now looked upon simply as embryonal defects which showed failure of union of the several embryonal processes and that he had collected cases from his own files and from the literature to show that they are only a part of a large group of process failures, not only in the lip but of the nose, the face, and the lower lip and jaw as well.

Case 1.—In this case the right and left maxillary embryonal processes have failed to unite with the median embryonal process which makes up the nose, prolabium and pre-maxilla. The difference between this case and the normal baby is that in the latter all the divisions have come together, while here they are all apart.

Case 2.—The pre-maxilla has been replaced in relation to the maxillary processes and the lip has been done by bringing the muscles underneath the skin and in front of the mucous membrane of the prolabium, the mucous membrane of which has been incorporated in the vermilion border of the lip. The body of the lip is coming out pretty well, but there is still trouble with the nostril. Dr. Ritchie said that the nostrils usually look alike in these cases although they may not be what the baby is entitled to.

Case 3.—This is a single harelip and cleft palate—the most frequent type of case with these various combinations. The alveolar process is not yet closed. This lip was done elsewhere and evidently was repaired without due effort to close the cleft in the bone; and, as can be seen, the nostril is very wide and flaring.

Case 4.—This is the same combination as Case 3, but the bone is in position and the nostril and lip, while not perfect, is a great improvement over the one just shown. Dr. Ritchie said that the technical details of the repair of the lip are the most controversial questions in surgery, but surgeons are gradually coming to the conclusion that the steps involve the consideration of two principles, one dealing with the active tissues of the body of the lip and one with the inactive tissues about the nostril.

Case 5.—This baby was operated on last Monday and the lip was repaired on the theory that the opportunity for future growth and development of this lip required the exact approximation of the muscle elements of the lip; so it was built puckered up, as you can see. The reason for this is that every lip has the physiological function of whistling and that this is the end-result of the action of all the muscle elements and, if these babies can be given the power to do this, presumably the other odd function of these elements of the lip will naturally follow.

Dr. Ritchie then showed a group of cases for the use of skin grafts and the repair of various contractures. One group, and the one most important from the standpoint of function, include the contractures about the joints. In the consideration of these cases there is a great difference between involvement of the flexor and extensor surfaces. In the former, of course, the deeper tissues must be definitely considered because there are more essential structures placed there than in the latter.

Case 6.—This boy was burned over a year ago, and Dr. Ritchie said it has taken practically all the time since to cover this enormous area, which, as could be seen, involved the right arm, the axillary space, the shoulder and on to the chest. The consideration of these enormous granulating surfaces is one of the very great problems in this field, not only from the standpoint of the patient but from the economic side of the case. The arm was put on an airplane splint and was extended, but even with all this preliminary care he has contractures at both folds of the axilla and a very extreme contracture at the elbow joint. The only thing which had been done for the patient so far was to skin-graft the shoulder, on which a full thickness skin graft was used. This was placed upon the granulating surface with a complete "take" and with a smooth area which approximates the normal skin. The rest of the area was grafted by the small deep graft suggested by Dr. Davis of Baltimore. Dr. Ritchie said this has no comparison with the full thickness graft in the nature of the cosmetic result, but, as could be seen, it has developed a definite epithelial covering. He said the next step in this case was to release the contractures at the axilla and also the release of the contracture at the elbow joint. In the latter there is greater opportunity than anywhere else for having involvement of the deeper structures; normally the elbow joint has the thinnest epithelial covering and it is not an uncommon thing to find that the contracture is due to deep-set adhesions about the joint; and sometimes it is necessary to elongate the biceps tendon, which, over such a long period as in this case, may be very definitely contracted. Hence, on the flexor surface of the elbow joint and the popliteal space, operations may develop into major procedures. Dr. Ritchie said as yet he had not studied this particular case sufficiently to be in a position to say what is necessary to be done to this joint.

Case 7.—This girl's arm was bound down to her side by wide scar bands over the thorax and she also had contractures at the axilla. A large contracture at the neck was taken care of and beautifully done by Dr. Waldron on the plan of the Z-plasty. By extension, the scar tissues are raised up into a band above the surrounding tissues. The band is then bisected and two flaps made. Then, by cross incision, flaps are made which, by fitting the flap on one side into the raw surface of the other, permit of increasing by at least fifty per cent the distance between the two ends of the contractures. Z-plasty was also done on the thorax. In this instance six flaps were cut and placed.

Case 8.—This case falls in another interesting group of the congenital deformities involving the consideration of moles, angiomata and tumors. This boy had an enormous mole involving the left eyebrow, one-half of the forehead, and extending upward beyond the hair margin. Dr. Ritchie said that to remove this mole and substitute a full thickness skin graft would exceed the possibilities of tissue transference; and while the full thickness skin graft is a wonderful adjunct it has some limitations as regards size. In this case the mole was diminished in size by successful partial excisions, and, in so doing, consideration was taken of the elasticity of the surrounding skin. On three occasions a full inch was removed along the middle of the mole, the tissues were undermined and the wound sutured. By so doing, it was possible to diminish the size of the mole to a point where it was possible to substitute a full thickness graft for the diseased tissue. The position on the forehead is one of the most favorable sites for a successful result because the bone of the forehead presents resistance to pressure of the graft and permits of perfect fixation, which, in Dr. Ritchie's opinion, is essential to success.

Case 9.—This case is one of contracture on the dorsum of the hand. The fingers were thrown back to a point impossible to illustrate at this time. The scars were removed and a full thickness skin graft substituted.

Dr. Ritchie said this was the third case of the full thickness skin graft which he had presented this evening—the one on the shoulder on a granulating surface, the one on the forehead, and this one on the hand; and in each one of these cases the graft presented the appearance of normal skin.

Case 10.—Dr. Ritchie said there had been several cases of lye burns about the mouth. This young lady had a resulting contracture to a point where it was impossible to put a spoon in the mouth. The plan of repair of this case was to break this circular band in two places. Dr. Ritchie said he had found that a single incision into a contracture would result in a condition that is even worse than the original, but if the band is broken in two or three places the tissues in between the incisions tend to re-vascularize and, even though there is a scar, the tissue will take on the aspect of normal skin. In this case the first step was to break this circular band, which was done at each angle of the mouth. Then the scar tissue was rearranged on the principle of the Z-plasty, with material improvement in the case. The patient then returned for a second operation and the bands of scar tissue were removed by the cut-and-suture method, with the result, as could be seen, of a full open mouth. The patient still had a band on the inside of the mouth which Dr. Ritchie said could be sectioned and a Thiersch graft placed on a mould. He said they had found that a Thiersch graft placed in the mouth will take on the aspect of mucous membrane although, of course, it will not secrete.

DISCUSSION

Dr. Willard White (Minneapolis) asked if this would also apply to the mucous membrane of the urethra.

Dr. Ritchie said he had just completed reconstructing a male urethra with a flap from the scrotum.

Dr. White asked if a Thiersch graft or a thin layer of epithelium were applied to the urethra it would take on the function of the mucous membrane.

Dr. Ritchie replied that he really did not know but he presumed it would if it could be fixed in position. A Thiersch graft can be used for the enlargement and lining of the nostril, but with the urethra he thought the problem would be to fix it in position until healing took place.

Dr. Carl W. Waldron (Minneapolis) presented the following patients:

Case 1.—Bilateral Resection of a Portion of the Mandible for Protrusion. This young man had a very marked protrusion of the mandible and had but two teeth that came in contact. A bilateral resection was done. There is now satisfactory occlusion and the patient has a good strong jaw. The wires are still in place but the twisted ends have been removed.

Case 2.—Restoration of the Cheek by a Skin Graft Lined Neck Flap. Stage 1. This patient has a pocket in the neck and one can see the skin graft lining of the pocket. The outline of the neck flap could also be seen. This condition is postoperative from carcinoma of the cheek. About six months ago the patient was unable to open his mouth because of an extra-articular ankylosis of the jaw due to scarring. This had been relieved by dividing the scars and skin grafting to prevent recurrence.

Case 3.—Restoration of the Cheek by a Skin Graft Lined Neck Flap. In this patient a flap from the neck was used to restore a large defect in the face. A double surface skin graft was first buried in the neck, as in Case 2. The cheek defect was acceptably closed by the flap, but it had been reopened along its upper border to give better access to an area of recurrence of the carcinoma.

Case 4.—Total Restoration of the Nose by the Forehead Flap. Stage 1. This flap as outlined has been raised and replaced on the skull on two occasions in order to make it better able to maintain its vitality with a considerably reduced arterial supply and venous return. The alæ could be seen on the flap. The extremity of the flap would be used to form the columella and line the vestibule.

Dr. William T. Peyton (University Hospital) presented a follow-up study of "Cases of Cancer of the Rectum Treated at the University Hospital Since 1924." Seventy-seven patients were found to have been treated from the beginning of 1924 to the present time. The present condition of every case had been determined. Twenty-two of the patients are now living. Lantern slides were shown giving the date of admission of each patient and his subsequent course. Lasting freedom from recurrence is most apt to follow the combined abdomino-perineal operation, and seventeen patients were operated upon by this method (Coffey operation performed). Four of these are still living: one 7 years, one 5 years, one 4 years, and one 3 years. However, the mortality by this procedure was high; in the 17 operations of this type there were 7 postoperative deaths. This operative mortality can probably be reduced in two ways: (1) Selection of one of the other types of combined abdomino-perineal operation instead of the Coffey procedure; (2) The use of spinal anesthesia instead of general anesthesia. W. E. Miles had reported a mortality of 36.2 per cent under general anesthesia, which was reduced to 9.4 per cent under spinal. Cases should be carefully selected for this extensive operative procedure and only good surgical risk patients accepted; the others should have some other lesser procedure.

Dr. Peyton then demonstrated several patients from the Tumor Clinic.

Case 1.—Miss M. M., aged 62, had a lesion which began at the medial corner of her left eye in 1919. It was at first treated with salves, and later in the same year some X-ray therapy was given. The lesion improved but did not entirely heal. It remained rather quiescent until October, 1928, when it took on rapid growth. She came to the University Hospital for treatment in April, 1930. (The condition at the time of her admission to the clinic was demonstrated by lantern slides.) X-ray at the time of admission showed some involvement of the left maxillary sinus and the floor of the left orbit and left frontal sinus. She was treated with deep X-ray therapy during 1930 on April 30, May 5, May 23, July 18, October 11, and December 29. She was given narcotics for pain but the pain has been subsiding and at present she is not taking as much.

Case 2.—Mrs. B. A lump appeared in the left breast April, 1930, and was excised locally one month later. It almost immediately recurred and she had a radical mastectomy in December, 1930. A few weeks later an enlarged left supraclavicular node appeared and she was referred to the University Hospital; 792 mc. hrs. of radium implants were inserted into this and it has disappeared.

Case 3.—Mr. L., aged 65, noticed in April, 1929, a roughening of the left cheek on the mucosal surface. In January, 1930, a small lump developed at the site of this roughening. In April he consulted a physician and it was excised. In July, 1930, he had radium elsewhere. In November, 1930, he was first admitted to the University Hospital with a local recurrence at the site of removal of the primary lesion. This recurrence was about 3 × 4 cm. in diameter and was attached to the mandible with fixation of the jaw so that he could not open his mouth. The skin in this region was ulcerated, as was also the mucous membrane. There were no palpable nodes. X-ray showed involvement of the mandible. Biopsy showed squamous cell carcinoma, grade 4. On November 29, 1930, excision of the mandible was done and this was followed by deep X-ray therapy. He has had no recurrence since this removal.

Case 4.—Mr. O., age 48, first noticed a slight soreness of the right cheek in 1921 while chewing tobacco. The surface was rough. In the summer of 1925 it began to grow larger, at which time it was cauterized by a doctor. Following this it persisted and grew, and became painful. He came to the University Hospital for treatment in October, 1926. Examination showed an irregular, rough, ulcerated lesion, 2 × 1 cm., inside the right cheek. There were palpable submaxillary nodes in the right side. Biopsy showed squamous cell carcinoma. Two thousand mc. hrs. of radium was implanted in the lesion in November, 1926. In January, 1927, he had excision of the glands in his neck. Biopsy of these glands showed no malignancy. In November, 1927, the local recurrence was treated with 3 mc. of radium. In June, 1929, leukoplakia was destroyed with the surgical endotherm. In October, 1929, he had a local recurrence which was excised with the surgical endotherm and the mandible was cauterized, as it seemed to be involved. In February, 1930, he developed erysipelas. In May, 1930, the entire right side of the mandible sequestrated and was removed, leaving a large defect in the right cheek. In November, 1930, a recurrence was treated with 1,000 mc. hrs. of radium. On February 24, 1931, he was re-admitted to the hospital and a recurrent lesion was excised, the lateral wall of the antrum being removed at this time.

Case 5.—Mr. O. W., aged 62, noticed in December, 1929, a feeling of fullness in the rectum and diarrhea. He saw a doctor in October, 1930, and was referred to the University Hospital for treatment. Examination at that time was as follows: mentally confused, marked pallor of the skin; blood examination showed hemoglobin 75 per cent and 3,480,000 red blood cells. An operable carcinoma of the rectum was found about 10 cm. from the anal opening; it was movable and about 5 cm. in diameter, limited to the anterior wall of the rectum. Biopsy showed adenocarcinoma, grade 3. It was decided not to attempt radical excision because the patient's general condition was so poor. A colostomy was performed. Three thousand five hundred mc. hrs. of radium in the form of implants and high voltage X-ray therapy was given. On January 23 there was no definite evidence of recurrence but some induration and he was given 1,000 mc. hrs. of radium in the form of implants. There is no definite evidence of carcinoma at the present time.

Case 6.—Mrs. A. D., aged 69, first noticed this lesion n 1918. She had no treatment for two years, then had plasters in 1920. This was followed by radium therapy. She came to this hospital in September, 1928, at which time there was a large flat ulcer of the right frontal region with involvement of the upper eyelid. The lids had been sutured. Biopsy showed basal cell carcinoma. She had been given deep X-ray therapy in December, 1928, but this did not heal the lesion probably because the cartilage was involved. In January, 1929, she had more treatment but the lesion still did not heal and in February she was advised to come to the hospital for endotherm excision. In March, 1929, she had more X-ray therapy. She then disappeared until October, 1929, in the meantime going to a "healer." In October, 1929, she was re-admitted to the hospital and a recurrence was then removed with the endotherm knife. In December, 1929, there was a persistence of the carcinoma which was removed with the surgical endotherm. She had no further recurrence until April, 1930, when areas were removed which were found to be mixed squamous and basal cell cercinoma. In May, 1930, further recurrence was removed with the surgical endotherm. In March, 1931, a biopsy was taken which again showed a recurrence. This was treated with 1,500 mc. hrs. of radium implants. The patient is now in an almost hopeless condition.

Case 7.—Male, aged 58, had irritation and soreness of the tongue in July, 1929. In October, 1929, he saw a doctor and was referred here for treatment. Examination at that time showed a red, ulcerated lesion in the posterior part of the left side of the tongue, 3 cm. in diameter. There was an enlarged gland in the upper part of the left side of the neck. In November, 1929, the patient received 800 mc. hrs. of radium implants to the lesion. This was followed by deep X-ray therapy. In February, 1930, a block dissection of the left side of the neck was done. Squamous cell carcinoma was found in the glands of the neck. The patient had a local recurrence in February, 1930, which was treated with 950 mc. hrs. of radium implants. There was local recurrence in August, 1930, which was treated with 800 mc. hrs. of radium implants. He had another local recurrence in January, 1931, which was treated with 2,000 mc. hrs. of radium implants.

Dr. Wilhelm K. Stenstrom (University Hospital) discussed malignancies especially amenable to X-ray and radium treatment. Dr. Stenstrom presented two cases as follows:

Case 1.—This man came in April, 1928, with a lesion on his hand. It was diagnosed squamous cell epithelioma in the Dermatology Clinic, and he was referred to the X-ray Therapy Department for treatment. A very heavy dose of X-rays was given and a second similar treatment was given two months later. If surgery had been used in this case it is doubtful if he would have had the full use of his hand.

Case 2.—This man came in June, 1930, with a lesion on the nose extending down on both sides. The ulceration was raised about 0.5 cm. and measured 3 cm. in diameter. It was diagnosed squamous cell epithelioma. The lesion was treated with gold radon implants into the raised edges and X-rays to the whole lesion. It has been healed since August, 1930.

Dr. Stenstrom said he wanted to call attention to another type of cancer best taken care of with radiation alone and that is cancer of the cervix. In this group radiation alone usually accomplishes more than surgery alone, but it is necessary to consider the various types. There are certain types that may be handled better by surgery and that is where the pathologist comes in to help the surgeon. Most groups of malignancies should be differentiated as to the grade of malignancy. As a rule the more malignant and fast-growing tumors do better with radiation; the slow-growing type are best taken care of with surgery.

DISCUSSION

Dr. Ivar Sivertsen asked how soon after radiation is surgery advised.

Dr. Stenstrom said that surgery usually was used first when combining the two, and if surgery is used after radiation one should give the radiation an opportunity to work—perhaps 10 to 14 days. He added that at the University Hospital surgery is not used in cancer of the cervix.

Dr. J. F. Corbett asked if any form of radiation was used in cancer of the breast.

Dr. Stenstrom replied that in certain cases radium is implanted after operation and X-ray therapy is used as a prophylactic postoperative treatment for all patients operated for cancer of the breast at the University Hospital.

Dr. Corbett asked if it was used before operation in these cases at the University Hospital.

Dr. Stenstrom replied that it was not.

Dr. Wallace H. Cole (St. Paul) demonstrated the "Use of Skeletal Traction in Conditions Other than Fractures."

In order to show how skeletal traction either by the use of Steinman pins or Kirchner's wire can be used in conditions other than fractures, numerous lantern slides were shown which demonstrated the value of this procedure in the following conditions:

1. Congenital dislocation of the hip in older children, as a preliminary to open reduction or to shelving.
2. Pathological dislocation of the hip, in order to overcome the shortening before stabilization or reduction.
3. Coxa vara, after osteotomy.
4. Shortening of leg due to infantile paralysis.
5. Congenital shortening of the leg.
6. Marked angular deformities of the lower extremities, either acquired or congenital.

The results in all these conditions, in selected cases, are apparently far better than could be obtained by less radical means. The pins and wire do not cause any irritation or discomfort if applied and taken care of properly. Although special apparatus is needed for the leg lengthenings, all the other procedures can be accomplished with the use of only the simple Thomas splint.

Dr. **Edward T. Evans** (Minneapolis) reported the following cases:

Case 1.—Arthroplasty of the Hip. The patient was a male, 44 years of age. Preservation of the integrity of the great trochanter during the operative procedure and disproportion between head and acetabulum were stressed.

Case 2.—A young man 21 years of age who, at the age of 11, developed a tumor of the knee which proved to be myxofibrosarcoma. Mid-thigh amputation was performed. (Specimen shown.)

Dr. Evans mentioned a case which he had operated on only that morning removing a large cystic hydroma of the knee joint. (Specimen shown.)

DISCUSSION

Dr. **Wangensteen** stated that these knee joint tumors are very interesting and that one other such case had come under his observation. The other case had been seen at the University Hospital several years ago and was thought at that time to be a hemangioma. Later the case had come under Dr. Colvin's care at the Ancker Hospital in St. Paul. Dr. Noble worked the tumor up from a pathological standpoint and found it to be a lipofibrosarcoma. They do not metastasize but are potentially malignant in that they tend to recur locally after removal. The only satisfactory treatment, therefore, is amputation.

Dr. Wangensteen felt that the injection of air after withdrawal of fluid from the pouch, in Dr. Evans' second case, was a unique manner of establishing the presence of continuity with the knee joint and was a significant principle in radiography of cysts and bursæ that has a wide range of usefulness and a method that had occasionally been used at the University Hospital in the recognition of such conditions over a five-year period.

Dr. **A. R. Colvin** (St. Paul) said he might discuss the second case from the point of view of difficulty in diagnosis. He had had a man at Ancker Hospital, 60 years of age, who had a tumor about three times the size of this one, and an interesting point about that was that he had been here some years before with an injury. The condition was diagnosed as a hematoma. He left the hospital and wandered around and came to St. Paul six years later. Dr. Colvin said they had at Ancker Hospital at the same time a man with a large swelling on the axilla and around the shoulder, with a diagnosis of carcinoma.

Their first case turned out to be a myxosarcoma and had an amputation done. Their second case was a large hematoma. In the first case the biopsy had been taken from a hemorrhagic area of the tumor, hence the confusion; and in their second case the biopsy was taken from an organizing area of the hematoma, hence the histological confusion. Amputation through the thigh was done in their first case and there is still no evidence of metastases in spite of the fact that it had existed such a long time; evidently it was not a very malignant tumor.

Dr. **Wangensteen** called attention to the fact that these knee joint tumors had been studied by Professor Wegelin, Director of the Pathological Institute in Berne, and that he found some of them to exhibit xanthomatous tissue.

Dr. **N. Logan Leven** (University Hospital) discussed the "Uses of the Implantation Method of Skin Grafting."

Dr. Leven demonstrated a method of skin grafting first described in 1920 by Welhelm Braun in Berlin and introduced into this country by Dr. Wangensteen in the fall of 1928 (reported by Dr. Wangensteen in the March, 1930, issue of Surgery, Gynecology and Obstetrics).

The method consists in the implantation of small pieces of skin, 2 × 4 mm. in size, directly into the granulations. The skin is usually obtained from the anterior aspect of the thigh. After the usual skin sterilization by iodin followed by a half-strength solution of sodium thiosulphate in 70 per cent alcohol, the area from which the skin is to be removed is anesthetized by infiltration with 1 per cent novocaine solution. The surface to be implanted is painted with a 2 per cent aqueous solution of mercurochrome. No anesthesia of the granulating surface is usually necessary. (Light ethylene anesthesia may be used if there is much pain.) Drawing the skin taut between two dinner plate knives or tongue blades, a Thiersch graft is cut with a straight edge razor or with a razor blade held in a hemostat. The size of the graft removed will of course depend upon the extent of the area to be implanted. With a fine sharp scissors the graft is cut into small pieces, about 2 × 4 mm. in size; these are placed on a sterile board covered by a towel. With a Kelly forceps an ordinary small straight round sewing needle is grasped "end on" so that the blunt end of the needle is free. The small implants which have been cut are then impaled with the blunt end of the needle and pushed obliquely into the granulation tissue until they disappear from sight. The needle is withdrawn, using a tissue forceps or another needle to retain the graft in place.

The grafts are implanted about 1 cm. apart, covering the entire granulation surface in this manner. By this method a large defect can be covered with a small amount of skin.

For a postoperative dressing vaseline gauze may be used; however, if the wound is infected and discharging pus, the ordinary Dakin's dressing is used, there being no danger of washing off the implants. About one week later small whitish areas appear at the sites of implantation. These small islands of epithelium grow rapidly and cover over the granulating surface.

The question arises why epithelial cysts are never found in this type of graft, since in the case of traumatic or experimental implantation of epidermis in the normal skin the well-known Reverdin's traumatic epidermic cysts develop. These implants are laid in a soft mass of granulation tissue and grow without injury or resistance along small clefts to the surface of the granulations. In the normal skin, on the other hand, the epidermis is interposed between the rigid fibers of the reticular part of the skin and tend to grow along the relatively large lymph spaces rather than in any other direction.

Case 1.—This patient had a disarticulation at the hip on February 11, 1931, for an extensive tuberculous infection of the head and neck of the femur and of the ilium with sinus formation. A rather long medial flap was used to partially close the defect. On the fourth day, however, a large part of this had to be sacrificed on account of a gas gangrene infection. On March 4, after granulations had formed, the stump was implanted by this method and, despite constant purulent drainage from the ilium, it is healing nicely.

Case 2.—This patient had a large defect following removal of the right scapula for a large mixed-cell sarcoma. This was implanted and healed nicely.

Case 3.—This patient on admission to the hospital last fall presented a large ulcer on the lateral aspect of the left foot following X-ray therapy. On four occasions this was widely excised by cautery and by sharp dissection in an effort to obtain a granulating base. Granulations at all times appeared indolent, unhealthy, and covered by a pellicle of fibrin. These granulations were implanted, using thicker implants than usual.

Braun has suggested, in using this method in sites where there will be traction or pressure, that the graft should be cut to one-half or two-thirds the skin thickness.

Dr. Leven showed a lantern slide exhibiting a large pressure sore in which the method had been employed. The patient was suffering from a paraplegia secondary to metastasis to the dorsal spine from a carcinoma of the cervix uteri, and developed a large decubitus ulcer over the sacrum. This was implanted and, despite pressure and incontinence of urine and feces, was practically healed at the time of her death seven weeks later.

Dr. Leven stated that the only condition requisite in using this procedure is that granulation tissue must be present in the wound. The method is effective in the presence of infection and does not require healthy granulation for growth. He stated that this type of graft has an absolute indication in those cases in which other types of graft would fail—in osteomyelitic cavities, chronic empyema cavities, and decubitus ulcers with undermining of the skin. The epithelial surface resulting from this type of graft is similar to that of wounds in which all the epithelium has been derived from the periphery of the wound, the implants not preserving their identity.

Since the fall of 1928 this method of skin grafting has been used in about 100 cases of all types—decubitus and trophic ulcers, varicose ulcers, osteomyelitic and chronic empyema cavities, amputation stumps, operative and traumatic defects, and burns. In 80 per cent of these cases the results have been very satisfactory. A further factor that commends the use of this method is that it may be used in ambulatory patients in the outpatient department.

DISCUSSION

Dr. Wangensteen stated that this technic of skin grafting was employed quite frequently at the University Hospital and that undoubtedly some cases had been grafted by this method in which others methods would have served the purpose just as well or better. In obtaining an epithelial covering over excavated defects such as osteomyelitic cavities, pressure sores, or deep empyema wounds, the method has no equal.

Dr. C. Donald Creevy (University Hospital) discussed "The Punch Operation for Prostatic Obstruction."

He reviewed briefly the history of attempts to relieve prostatic obstruction by transurethral operations, beginning with the catheter knife of Guthrie in 1834, and then later the instruments of Mercier and Bottini. He pointed out that these early attempts failed because surgeons failed to appreciate the necessity for preliminary drainage of the bladder, and because the obstructing gland could not be inspected directly. Young's punch, brought out in 1911, obviated the second difficulty, while experience had eliminated the first. He prefers the Braasch instrument because of the ample size and direct illumination which permit adequate visualization of the urethra and the removal of large pieces of the gland; bleeding is controlled by electrocoagulation of the individual vessels under direct vision.

Dr. Creevy recognized four indications for the use of the prostatic punch, namely, the median fibrous bar at the vesical outlet, whether inflammatory, postoperative, or carcinomatous (palliative); postoperative infection of the surgical capsule; small lateral lobe hypertrophies, and in certain lesions of doubtful nature the instrument may be used to secure tissue for microscopic examination (recognition of early carcinoma).

He cited the low mortality of the punch operations in the hands of experts (Young, Caulk, Bumpus)—three-tenths of one per cent in over 1,000 cases, but regretted that studies of late results in large series of cases were not available.

He showed three cases illustrating different problems.

Case 1.—The patient had had a persistent suprapubic fistula and total urinary incontinence for 18 months after prostatectomy done elsewhere. Removal of a cicatricial postoperative bar by the punch together with postoperative dilatations of the urethra had resulted in complete return of continence.

Case 2.—This was the case of a man with an inflammatory bar who had been subjected to the operation 48 hours before. He was already up and about in comfort and was shown to illustrate the minor character of the postoperative reaction in many cases.

Case 3.—This man was admitted with auricular fibrillation and cardiac decompensation complicated by a small lateral lobe hyperthrophy of the prostate with 150 c.c. of foul residual urine. After the compensation had returned under the care of the Medical Service, the punch had been used and the residual urine relieved in a situation in which prostatectomy would have proved hazardous.

Dr. Creevy pointed out that Caulk and Bumpus were using the punch in large lateral lobe obstructions with good immediate results, but could not predict whether these would be permanent.

DISCUSSION

Dr. E. A. Regnier asked what method is carried out in drainage of the bladder following the punch operation.

Dr. Creevy said that he had been in the habit of electro-coagulating each bleeding point and omitting the indwelling catheter. If there is any evidence of postoperative urinary retention it is relieved by catheterization.

Dr. Theodore Sweetser asked about cases reported in England of obstruction after prostatectomy and if Dr. Creevy would consider that this was a good procedure in relieving that scar tissue.

Dr. Creevy stated that he had carried this out in four cases with very satisfactory results, but that his experience extended over only one year and he could not say anything about the late results.

Dr. H. A. Carlson (University Hospital) presented two cases of malignant melanoma with regional metastasis in which operation had been performed.

Case 1.—This patient was a male 63 years old. In July, 1929, he first noticed that he had a pigmented mole on the back of his neck. In January, 1930, he observed that he had small masses on the right side of his neck. The glands continued to enlarge and in May his physician removed a specimen for microscopic examination. This was sent to Dr. E. T. Bell, who returned a diagnosis of malignant melanoma. Excision of the primary melanoma and block dissection of the neck was performed by Dr. Wangensteen on May 14, 1930. Subsequently he had deep roentgen therapy. He was followed in the dispensary and in November a nodule was removed from the right deltoid region which was found to be a recurrence. Since that time no evidence of recurrence has been found. He has gained 25 pounds in weight since the operation.

Case 2.—This patient was a male, 58 years of age. He had had a small subcutaneous nodule on the tip of the left ear for many years. It was injured in June, 1928, by a wood splinter and the resulting ulcer failed to heal. In July, 1929, he went to the Minneapolis General Hospital because of pain. On biopsy, the diagnosis was malignant melanoma. He was operated on by Dr. W. T. Peyton at the University Hospital August 5, 1929. The primary lesion was excised and a block dissection of the neck performed on the left side where enlarged nodes were present. X-ray therapy was instituted. There has been no evidence of recurrence.

DISCUSSION

Dr. Wangensteen stated that the early excision of the regional lymph nodes in malignant melanoma demands emphasis. So frequently one sees instances in which the local lesion had been excised and nothing done to the local nodes. Just as the excision of the regional lymph nodes is an important principle in the treatment of carcinoma, Dr. Wangensteen felt that the early removal of the regional lymphatics together with the local lesion would bring about better results. He admitted that melanoma may not always spread by the lymphatics, but felt that it occurred with such regularity that the excision of the lymph nodes should be the accepted mode of dealing with malignant melanoma of the skin. He stated that their experience at the University Hospital indicated that these tumors are not radio-sensitive. In the summer of 1928, Dr. Wangensteen said that Mr. Sampson Handley of the Middlesex Hospital in London had shown three instances at the International Cancer Conference in which this "complete" operation had been done. Handley removed the intervening lymphatic vessels in the fascia as well. All of these patients were quite well and one had survived for about 18 years.

Dr. A. T. Mann recalled a very interesting case that would bear out the lack of malignancy in some of these melanomata. A girl about 13 years old came in with a melanoma on the back which was like a very large boil in shape and had considerable mass to it. It was not one of these moles, although it may have been to start with. It was fairly widely excised but in excising it one could see black spots way back in the muscles of the back. It was decided that this was too widely distributed for excision of the secondaries and she was closed up with those black spots still there. She walked into the office two years later, apparently in perfect health. Her back was smooth and she showed no signs of recurrence.

Dr. Wangensteen said that a previous experience that had terminated unfavorably had taught him that the closure of the skin wound was an important item in protecting the patient with a deep wound from infection and, in the case demonstrated by Dr. Carlson, he had performed an atypical Z-plasty at the initial operation to help cover the defect.

Dr. Horace G. Scott (University Hospital) discussed "The Nutrition Problem in Fistula of the Small Intestine," and showed a boy, 13 years of age, with the following history:

In January, 1928, the boy had an operation for ruptured appendix. The appendix was removed and drainage instituted. He drained for 10 days. Six months later he developed an incisional hernia and was reoperated, at which time adhesions were found. He was fairly well until November, 1930, when he developed intermittent crampy, colicky pains in the abdomen followed by nausea and vomiting. His symptoms persisted for four days before he entered the University Hospital. On admission he was found to be very ill; his pulse was 164 and he was quite dehydrated. There was considerable distention and diffuse tenderness, muscle spasm and rigidity present over the entire abdomen. Flat plates of the abdomen revealed gas in the small intestine. A preoperative diagnosis of intestinal obstruction was made, probably of the strangulating type. At operation a reddish, black mass was found which proved to be a two-foot loop of lower ileum. A Mikulicz exteriorization of the bowel was done and the strangulated segment resected. Catheters were placed in both segments of the bowel and the content from the proximal loop was run into the distal loop under the influence of gravity. After a few days, however, the catheters became loose and the introduction of the proximal loop content into the distal loop was found to be impractical. The boy lost approximately 1,500 c.c. of food and fluid a day from the proximal loop. As a result he steadily lost weight on a general diet, his weight falling from 87 to 49 pounds over a six-weeks' period. The last two weeks of this period he was placed on a special high carbohydrate diet. This diet apparently did not help to check his falling weight. In fact, it apparently aggravated peristalsis. Observation of the proximal loop revealed a forceful frequent discharge of yellow fluid and undigested food occurring within thirty minutes after eating. The diet was then changed. The carbohydrates were cut down and the emulsified fats were increased by giving the boy a glass of half milk and cream at frequent intervals. Within a couple of days after this change in diet had been effected, the discharge from the proximal loop was observed to be less forceful, and to contain less and less undigested food. After a week's time it was slowed up to such an extent that after eating a meal it was two or three hours before any fluids were discharged. The boy then began to regain his lost weight. Three weeks later he was re-operated upon and the continuity of the gut was re-established. He then went home. Ten days later he had another acute obstruction attack. The abdomen was again opened. This time a large loop of jejunum was strangulated. After release of the strangulating band of adhesions the color of the gut returned. The abdomen was then closed with enterostomy drainage of the proximal loop and the boy made an uneventful recovery.

Dr. Scott stated that this case illustrates one important fact which is overlooked in the feeding of the fistula case, namely, that carbohydrates, although easily assimilated, enhance the peristaltic activity of the bowel; whereas emulsified fats cause a slowing of peristalsis which allows more time for the absorption of food and fluids lying within the gut.

DISCUSSION

Dr. E. A. Regnier asked if it had been possible at the second operation to determine where the site of the original enterostomy had been.

Dr. Wangensteen said it was about two feet from the cecum and that, whereas in adults no difficulty is to be anticipated from such a fistula, children notoriously stand small intestinal fistula of a complete nature very poorly. He said in the literature instances of decline in health and loss of weight are to be found reported after intestinal resections and anastomoses that an adult would well tolerate.

One other point relative to the case presented by Dr. Scott, he felt should be emphasized, viz., the value of high protein feeding in such instances. There was a good urinary output on an oral intake of fluid, but the tissues would not retain water until there was a liberal assimilation of protein. Then the normal turgor returned to the skin.

Dr. Wangensteen explained that Dr. McQuarrie, Chief of the Pediatrics Department in the Hospital, had rightfully called attention to the necessity for high protein feeding in this boy, and the boy's subsequent gain in weight was undoubtedly due in large measure, he felt, to this suggestion of Dr. McQuarrie.

Dr. Ralph Knight (Minneapolis) discussed "Selection of Anesthetics."

Spinal anesthesia, he stated, has taken a very important place in all operations below the diaphragm, and its advantages are so great that the tendency is to increase its use for all such operations which are not so minor as to be done with very brief gas anesthesias or very simple block infiltration. It affords a degree of relaxation not obtained by inhalation anesthesia.

Probable contraindications are: marked hypertension and hypotension, especially with debility from wasting or toxic illness, shock or hemorrhage. These are, however, contraindications for other anesthetics except possibly local or block anesthesia and probably the use of spinal anesthesia with very careful and improved technic will be gradually extended to the poorer risks.

Spinocaine had been used almost exclusively because it was thought best to use one method until a fair-sized series had been run, according to Dr. Knight. There had been a few failures and some had not lasted long enough for the operation. His personal impression is that spinocaine anesthesias tend to last longer than simple novocaine spinals, but that spinocaine exhibits a few more failures of sufficient anesthesia than does novocaine. Theoretically, at least, there is a little less margin of safety with spinocaine because of the technic of raising the head of the table until the desired level of anesthesia has been reached. Practically, this is probably neutralized by meticulous care in watching the blood pressure and lowering the head well in case of a drop below 70 per cent of the orginal, or in any case below 90 mm. Preliminary ephedrine is still given, and epinephrin in case the blood pressure falls, because it was felt that the patients are made more comfortable and get along better. Spinal anesthesia has not been used for work above the diaphragm, Dr. Knight stated. When spinal anesthesia must be reinforced by inhalation, ethylene is the agent of choice as it is usually sufficient without ether.

Ether is still the anesthetic of choice for a large number of operations about the head, especially in children, and will probably remain so unless alkoform or some other agent proves of greater value. Chloroform is often the agent of choice when deep anesthesia is needed for the use of the cautery about the head.

Local anesthesia has a wide field and is used liberally above the diaphragm, frequently being supplemented with a gas, especially for neck and chest work, the choice for the supplementing gas being ethylene.

Special anesthetic methods such as rectal and intravenous administration have not been found serviceable enough to be used to any great extent. They have a distinct field for operations which make local, spinal, and inhalation anesthesias impractical to administer. Ether by rectum is felt to be the most satisfactory in this field. It has a special indication for brain surgery as inhalation anesthesia has been found to increase the intracranial pressure. Rectal anesthesia has one great disadvantage in that recovery is sometimes very prolonged and the patient must be closely watched all this time to prevent pharyngeal occlusion.

The following figures show the anesthetics which have been selected for various regions and operative procedures during the past year (March 1, 1930, to February 28, 1931) at the University Hospital:

3,703 anesthetics exclusive of obstetrics, but including all other general and special surgical services.
14 different anesthetic drugs.
50 different combinations.
120 H. M. C., 17 per cent reinforced.
23 avertin, colonic, 60 per cent reinforced—all head, neck and bronchoscopies.
44 ether, colonic, 57 per cent reinforced—all head, neck, upper extremities and spine.
482 cocaine, including 20 eye, 47 nose and throat, 50 bronchoscopies, 365 cystoscopies.
992 novocaine infiltration, 22 per cent reinforced.
22 novocaine, spinal, 22 per cent reinforced.
10 novocaine, sacral, including 8 prostatectomies.
778 spinocaine, spinal, 15 per cent reinforced.
450 nitrous oxide basic, 38 per cent reinforced.
361 ethylene basic, 27 per cent reinforced.
339 ether inhalation.
20 chloroform, all about head, except 2 bronchoscopies.
15 ethyl chloride, including 5 cystoscopies.

By Regions:

126 upper abdomen: 61 per cent spinocaine alone; 34 per cent spinocaine plus inhalation; 5 per cent inhalation alone.
381 lower abdomen: 56 per cent spinal alone; 12 per cent spinal plus inhalation; 2 per cent novocaine infiltration; 29 per cent inhalation alone.
511 cystoscopies: 12 per cent H. M. C.; 71 per cent cocaine; 7 per cent spinal; 9 per cent inhalation.
142 prostatectomies and cystotomies: 71 per cent H. M. C.; 4 per cent spinocaine; 2 per cent spinocaine plus inhalation; 5 per cent novocaine, sacral; 14 per cent novocaine infiltration; 18 per cent inhalation.
967 below diaphragm—outside of abdomen and bladder: 30 per cent spinocaine; 2 per cent spinocaine plus inhalation; 1.4 per cent novocaine, spinal; 5.6 per cent novocaine infiltration; 60 per cent inhalation.

Regions above the diaphragm have not been tabulated for this report because the wide variety of operations done and the wide variety of anesthetic combinations used would make it too voluminous.

There were six deaths during the year in which the anesthetic should be evaluated as to whether it was a cause or contributing cause. All were extremely poor risks.

Case 1.—A very toxic man, aged 68, died under spinocaine anesthesia during operation for a large subdiaphragmatic abscess from a perforated duodenal ulcer of more than a week's standing.

Case 2.—A frail woman, aged 42, died under novocaine and ethylene anesthesia for thoracoplasty for pulmonary tuberculosis. She had acromegaly, was a very poor risk and died as the incision was made.

Case 3.—A frail woman, aged 46, died suddenly after 95 minutes of satisfactory ethylene anesthesia for operation for rheumatic contractures of the knees. Autopsy showed brain tumor with conus herniation of cerebellum into foramen magnum.

Case 4.—A man, aged 55, who had a very extensive carcinoma of the tongue died after only a few minutes of ethylene for ligation of the external carotid artery.

Case 5.—A man, aged 67, who had previously had extensive resection of the tongue, lip and mandible for carcinoma died after 10 minutes of chloroform anesthesia just as cauterization of a recurrence started.

Case 6.—A man, aged 72, had his maxilla resected under colonic ether and died 8 hours later before he had entirely recovered from the anesthesia. It was believed that his pharynx might have become occluded during a brief time when the attendant was away.

Dr. Knight stated that in each of these instances there were contributing factors and not in a single instance could one say arbitrarily that the anesthesia alone was responsible.

Dr. Melville H. Manson (University Hospital) discussed "Gas Bacillus Infection" with special reference to its occurrence postoperatively in cases of preëxisting gangrene and chronic ulcers.

There had been 9 cases of gas gangrene at the University Hospitals during the past two years. Five of these followed operative procedures and two in particular led to further investigations of the infection. These two cases developed in amputation stumps. The operations were performed for chronic, painful ulcers, which had resisted all conservative treatment. Two of the other cases were in patients who had preëxisting gangrene. The only deaths in the nine cases were the two which developed following amputations for chronic ulcers.

Dr. Manson said that the literature contained only a few references to the development of gas gangrene in conditions of this sort. He had cultured a series of chronic ulcers and found pathogenic, gas-producing anaërobes in approximately 30 per cent.

He stated that the use of polyanaërobic or specific anaërobic antitoxins had not been accepted unreservedly by the profession. Evidence was presented which showed the efficacy of the antitoxins. During the World War Saquepee gave polyanaërobic antitoxin to 319 wounded men with a resulting incidence of gas gangrene of 1.17 per cent. In a control series the incidence was 7.2 per cent. In a series of 191 developed cases, the mortality in those treated with antitoxin was 13.9 per cent, while in the same region the mortality of the untreated cases was 75 per cent. Ivens gave a polyanaërobic antitoxin to 433 cases in which there were

30 cases of gas gangrene when first seen. In this series there was one death. Henry and Lacey injected 50 guinea pigs with cultures obtained from cases of gas gangrene. Of this number 44 were pathogenic. To the 44 guinea pigs they gave antitoxins of Bacillus welchi and Vilrion septique, which protected 33 of the animals. To the 11 non-protected animals they gave antitoxins of Bacillus edematiens which protected six. From the five unprotected pigs, cultures of Bacillus fallax were obtained in two, and three had unidentified organisms.

Dr. Manson said that the principles of surgical treatment were well established but emphasized the point that no tourniquet should be used when amputation is done. A case was related in which the shutting-off of the circulation for only a few minutes was responsible for the development of a case of gas gangrene developing in a preëxisting gangrene.

He believed that chronic ulcers should be included with preëxisting gangrene as possible source of gas bacillus infections following operative procedures.

Dr. W. A. O'Brien (University Hospital) told of the development of the Pathological Department of the University Hospitals. While an integral part of the Department of Pathology of the Medical School, it functions as a separate unit.

There were 645 tissues examined in 1925. In 1930, the number had grown to 2,331. Approximately 225 examinations are being made monthly during the present year. During the same time postmortem examinations increased from 83 to 218. Approximately 24 examinations per month are being done this year. Part of this increase in autopsies is due to the increased bed capacity and part to an increased percentage of permissions (53.2–78.4 per cent). The University Hospitals are among the first 10 in this country in percentage of autopsies. The Mayo Clinic, the Minneapolis General Hospital and the University Hospitals have the highest state percentage of any group in this country or Canada. Much of the percentage increase is due to the splendid coöperation received from the hospital services.

All tissues removed at operation are routinely examined (except tonsils and adenoids, which are done on request). Surgical pathology has undergone a distinct change due to the increased number of biopsies and the development of a uniform terminology for clinical pathological correlation. The diagnosis of chronic appendicitis is not made. Appendices are grouped as follows: (1) No active inflammation (interval operation or removal at another operation); (2) Peritonitis (arising from within or without); (3) Acute suppurative appendicitis; (4) Obliterated appendix. By using this method excellent diagnostic and prognostic correlations are obtained.

Routine curettage and cervical biopsy are done on all bleeding women and those who have a cervical lesion. A distinct type of endometrium showing hyperplasia and cysts (Swiss cheese) is frequently found near the menopause. It is apparently due to ovarian changes (granulosal cell) and responds to radiation.

Thyroid glands are grouped under a few headings: (1) hyperplasia; (2) adenomatous; (3) colloid; (4) thyroiditis, and (5) malignant. No attempt is made to predict the type of disease in the patients. Patients with glands showing inflammatory changes are routinely followed for signs of hypothyroidism.

Dr. O'Brien said that tumor grading (typing) is here to stay. It has always been done by most pathologists. Giving numbers to various types is helpful in comparing the work of various investigators and attempting prognosis—tumors that are less malignant (types 1-2) and more malignant (types 3-4). Type 1 is usually borderline malignancy. Type 2 is fairly definite. Types 3-4 vary because some men classify by the degree of differentiation and others by the most malignant part; taken together they constitute a rather uniform group in the various reports in the literature.

Brain tumors are classified by the Cushing-Bailey method; some are easy to group (spongeoblastoma, medulloblastoma, and astrocytoma) while others are more difficult.

Certain types of specimens require a different number of sections. Apparently all appendices should have three sections—base, middle and tip. Large ulcers of the stomach and suspicious prostate glands require an unusually large number. In one of their cases at the hospital more than 40 sections were made of a large gastric ulcer before malignancy was found.

Breasts showing diffuse induration (after 25) present a diagnostic problem. Surgeons do not hesitate to remove a single definite lump for opinion, but are apparently content with a diagnosis of diffuse cystic disease when diffuse lumps are present. This method has been abandoned at the University Hospitals and all definite diffuse lumps are removed for opinion. Diffuse cystic disease may mask carcinoma. Recurrent tumors of all types are removed for diagnosis and prognosis. Some of them are of low grade malignancy and secondary operations may be done with benefit to the patients. Centrifuged fluid and needle biopsies are on the increase. Ten years ago one-third of all biopsies were benign and two-thirds malignant; today conditions are completely reversed. Special pathological services have been developed in the Division of Dermatology under the direction of Dr. Henry E. Michelson; in the Division of Neurology under the direction of Dr. J. C. McKinley; in the Division of Ophthalmology under the direction of Dr. Walter E. Camp.

There are three full-time Fellows on the Pathology Service at the present time: Drs. O. S. Randall, B. J. Pearson, and E. C. Hendrickson. Under supervision they examine and report all surgical specimens and do the autopsies. In addition they assist in preparing material (case reports and literature abstracts) for the weekly general staff meeting, and show the surgical specimens and microscopic slides at the weekly surgical pathological conference. All are planning surgical careers.

Dr. O'Brien stated that the Department of Pathology of the University Hospitals is showing a healthy growth. The diagnosis of biopsies constitutes more than one-half of the work. Experience in surgical pathology and postmortem examinations should be part of the training of every surgeon. Opportunities are provided for three full-time Fellows at the University Hospitals at the present time.

Dr. O. H. Wangensteen (University Hospital) presented a group of thoracic cases. The first group illustrated interesting features of empyema.

Case 1.—The first patient was a girl of three, who had recently had pneumonia. Later fever recurred and pus was aspirated from the right chest. The X-ray films showed a density over the middle portion of the right lung with a clear costophrenic angle. The impression from the films was that an interlobar empyema in the main fissure was present. A needle was inserted in the fifth intercostal space and 35 c.c. of a thick pus was obtained in which the pneumococcus was demonstrated. Two subsequent tappings were negative and, because of continued fever of 101° to 103° F., the fifth rib was resected. A large amount of pus and a large fibrin plug about the size of a man's hand was obtained. A drainage tube was inserted and the fever promptly came down. A subsequent X-ray plate showed no pneumothorax corroborating the impression of an encapsulated empyema. Irrigation of the small cavity with Dakin's solution together with blowing on bottles, Dr. Wangensteen felt, should quickly expand the lung and obliterate the cavity. The fibrin plug had prevented successful aspiration, in his opinion. Whereas aspiration, as recommended by Brenneman, is a commendable feature of empyema treatment in infants, Dr. Wangensteen felt that drainage in older children was the wiser plan.

Case 2.—Dr. Wangensteen referred to another case with an interlobar empyema and demonstrated X-ray films. The patient was a boy of 8, who had become ill with pneumonia in December, 1929. After convalescence, the fever recurred, and in May, 1930, operation was performed elsewhere for empyema of the left chest. A free pleural space and no pus was found at operation. Drainage was instituted but without effect. In August, 1930, the boy was admitted to the University Hospital with a steeple-chase type of temperature. There was no sputum. X-ray examination showed a fluid level with air above it. The costophrenic sinus was clear. The absence of sputum and the presence of air in the chest ruled out a lung abscess and a diagnosis of an encapsulated empyema was made. At the first operation, a free pleural space was again found and two ribs were removed and an iodoform gauze tampon was placed over the parietal pleura. Eight days later the wound was opened up and considerable pus was evacuated by incision after needling the thickened membrane overlying the encapsulation. There was prompt improvement and the boy returned to school.

Case 3.—The next patient was a boy of 24 years upon whom Dr. Wangensteen had performed decortication to obtain expansion of the lung for recurrent empyema. During the preceding nine years the patient had been operated upon six times for acute empyema. The patient had promptly gotten well following each operation but he had never stayed well because of an unobliterated empyema cavity. X-ray films, made after the injection of iodized oil, demonstrated that the sinus tract extended from the lower right lateral chest wall up toward the hilum of the lung. It was Dr. Wangensteen's first impression that the lung would be atelectatic after so many years and he believed that the chest wall would have to be brought to the lung by the Schede deribbing operation. At the initial procedure segments of five ribs were removed and a large dinner-plate sized area of parietal pleura more than an inch in thickness was removed. This procedure failed to obliterate the cavity completely and five weeks later the wound was opened again. In the interim the patient had blown on bottles in an effort to expand the lung but without any result. At the second operative procedure a membrane about 2 mm. in thickness, which at the initial operation was thought to be the visceral pleura, was incised. It was found that this membrane could be peeled off the lung much in the manner that one peels an orange. The lung expanded immediately and filled the wound; there was no bleeding and the restraining membrane was removed without breaking into lung substance. A Z-plasty was employed to cover the skin defect at the conclusion of the operation. Because of tension the skin closure gave way in part and when granulations later formed over the lung, skin implants were used to fill in the defect. The cavity has been completely obliterated and the patient has returned to work. Dr. Wangensteen stated that he had subsequently employed the decortication method (Delorme procedure) in other cases of empyema with complete satisfaction. He had been surprised at the minimal amount of bleeding and stated that the patients were pleased in being spared the greater deformity of the chest wall of the Schede operation.

The next group of cases shown by Dr. Wangensteen were of suppuration within the lung.

Case 4.—A women, 27 years of age, in January, 1931, developed a parametritis after an abortion. About three weeks ago she was brought to the University Hospital and admitted to the gynecological service because of a continued septic type of fever. Examination at that time showed a fixed uterus with dense adnexal masses. There was also slight tenderness and rigidity in the lower abdomen. Later the patient developed pain in the chest and X-ray examination showed an infiltration in the lower right lobe and an elevated diaphragm which was found to be immobile on fluoroscopy. An X-ray diagnosis of subphrenic and pulmonary abscess was made. Findings of a pneumonia were present in the lower right lobe. The patient had a persistently high fever and an extremely rapid pulse and appeared very ill. The question arose as to whether drainage for subphrenic abscess should be instituted. Physical examination failed to demonstrate any tenderness in the subhepatic or suprahepatic areas on the right side. Aspiration of the pleural space obtained no fluid as is often present when a subphrenic abscess exists. Aspiration of the subphrenic space failed to obtain pus. It was, therefore, felt that the mere presence of a high fixed diaphragm could not be considered conclusive for the presence of a subphrenic abscess. Postural drainage was instituted and the patient began expectorating a foul purulent sputum. The temperature has gradually receded and the patient's condition has markedly improved. Dr. Wangensteen said there were two possible explanations for the development of the lung abscess; one is that it was metastatic in origin; the more likely explanation would appear to be that the bronchopneumonia resulted in a residual abscess. The actual mechanism of the origin of the lung abscess might perhaps never be apparent, but the absence of tenderness over the lower chest on the right together with failure to obtain fluid from the pleural cavity and pus beneath the diaphragm, Dr. Wangensteen felt, militated against its origin from a subphrenic abscess.

Dr. Wangensteen referred to the fact that subphrenic infections frequently make their way through the diaphragm, whereas intrapleural infections rarely if ever reach the peritoneal cavity by direct extension. Küttner has shown that the lymphatics of the subdiaphragmatic peritoneum perforate the diaphragm, affording an explanation for the frequent presence of a transudate in the pleural cavity, accompanying subdiaphragmatic suppuration. Dr. Wangensteen related that he had recently seen on the Gynecological service a patient who had developed a diffuse peritonitis from the sudden perforation of a residual pelvic abscess into the peritoneal cavity. Later empyema developed. At autopsy a perforation of the left diaphragm near the esophageal aperture disclosed its origin.

Dr. Wangensteen referred to a patient who had recently been operated upon for a perinephritic abscess at the University Hospital who had developed a lung abscess by extension through the diaphragm. It, too, cleared up spontaneously with postural drainage as in the instance of the lung abscess just demonstrated.

Case 5.—A woman of 28 years was then shown, who had been sent to a sanatorium for tuberculosis in the fall of 1929 because of cough, fever, night sweats, weakness, and sputum. These symptoms had begun three weeks after tonsillectomy under ether. At the sanatorium numerous sputum examinations failed to reveal tubercle bacilli and a diagnosis of lung abscess was made. Pneumothorax was instituted and the patient improved but the fever continued, though in lesser grade, and the density in the lung persisted. She was admitted to the University Hospital early in 1930. Three bronchoscopic aspirations were done and the patient was dismissed in May, 1930, as well. Later in the summer she returned to report that she had had a small hemorrhage. An X-ray film then demonstrated a small cavity in the previously consolidated area. This has since healed and she has remained quite well.

Dr. Wangensteen related that another patient had recently returned for observation whom he had treated because of a lung abscess in the upper right lobe in January of this year. On postural drainage it had entirely cleared up and the X-rays now show the rather large cavity initially present to be healed.

Case 6.—The history of a patient, aged 25, who was then in the University Hospital but too ill to be shown, was briefly reviewed. The patient had been successfully operated upon at another hospital for acute suppurative appendicitis with local peritonitis. During the convalescence a central type of lung abscess developed in the lower lobe on the right side. Pneumothorax was given and considerable sputum was evacuated with marked improvement. Two other refills were given and the patient though not yet ambulatory left the hospital apparently getting along very well. A few days later the boy became very ill again. He was admitted to the University Hospital a few days ago with a persistently high fever, rapid pulse and foul bloody sputum. He had been irrational since admission. X-ray examination revealed a cavity in the apex of the lower right lobe. There was still a little air in the pleural space with no evidence of an exudate. An attempt had been made to reëstablish the pneumothorax before admission to the hospital but the attempt had not been successful. Three weeks had intervened since the last refill. Examination of the sputum after washing showed fusiform bacilli and spirilla present in large numbers. A subsequent X-ray examination showed spreading cavitation in the entire right lung. A diagnosis of pulmonary gangrene was made, due probably to secondary invasion from organisms in the mouth. The patient had been given neoarsphenamine intravenously, but without apparent effect.* Kline and Berger, of Cleveland, Dr. Wangensteen stated, had been enthusiastic about the treatment of pulmonary gangrene with arsenicals. Most chest surgeons, however, he stated were conservative in their estimate of its value.

It should be stated that abscesses centrally located in the lung already in communication with a bronchus, as in this instance, are the only ones in which pneumothorax is indicated. When pneumothorax is employed in the compression of an abscess located in the periphery of the lung, the hazard of empyema is invited. Though Whittemore and Balboni, in 1928, found a large number of instances reported in the literature in which pneumothorax had been highly successful in dealing with lung abscess, they had only two successes in 18 cases. It need scarcely be mentioned that aspiration of a suspected lung abscess for diagnosis through a nonadherent pleura is a dangerous procedure.

Case 7.—The X-ray films were demonstrated in the case of a woman of 40 years, who in July, 1930, developed chills and fever, followed by cough and expectoration of foul sputum about ten days after tonsillectomy under ether. She had been admitted to the University Hospital in September, raising about 500 c.c. of sputum a day. The patient's appetite was poor and there had been considerable weight loss. The temperature ran as high as 102° F. daily. Postural drainage and repeated bronchoscopic aspiration were without effect. The abscess was represented by a diffuse consolidation of the upper two lobes of the right lung. Pneumothorax was ineffectual. In October, external drainage was done, the surgical endotherm needle being employed to give hemostasis. Two operative procedures were necessary to give adequate drainage in the carnified lung. The sputum quickly diminished to a small amount and the patient became afebrile. She has gained in weight and at the present time has no sputum. The process in the lung has been slow in resolution and has not entirely cleared up. Whenever the patient "catches cold" she has 10 to 30 c.c. of sputum for a few days. As long as there is any trace of consolidation persisting in the lung on X-ray examination a small tube will be worn to keep the wound open. The bronchial fistulæ present will in all likelihood close spontaneously. In event they do not, a muscle flap may be employed to close them.

---

*Note: This patient has since died.

Dr. Wangensteen stated that in his experience fully 50 per cent of acute lung abscesses healed under conservative treatment of bed rest, postural drainage, bronchoscopic aspiration and compression by pneumothorax in selected cases; one chronic abscess of almost a year's duration in this series was completely healed following bronchoscopic aspiration. In those in which conservative measures fail, external drainage must be done.

Dr. Wangensteen said that satisfactory experimental evidence had finally been adduced to substantiate the opinion long held by clinicians that the majority of abscesses are due to aspiration of a foreign body or septic material into the lung. Tonsillectomy under ether is probably the most frequent single cause in the development of lung abscess. After loss of the swallowing reflex in deep ether anesthesia, blood is aspirated into the lung. The same may occur with poor hemostasis when tonsillectomy is done under local anesthesia.

A group of cases with bronchiectasis was next demonstrated.

Case 8.—A girl of 13 years, admitted to the University Hospital about 4 months ago, gave a history of having had whooping cough six years before, since which time there had been cough and sputum. In winter the patient has exacerbations of her complaint. There has been daily slight fever running usually up as high as 100.8° F. The sputum varies between 90 and 350 c.c. Lipiodol filling of the bronchi by the passive method of Ochsner showed cylindrical dilatation of all the bronchi of the left lower lobe with a few saccular dilatations present. There was slight dilatation of a few bronchi on the right but the disease was preponderantly unilateral. A left phrenic exeresis was done with some diminution in the sputum and slight general improvement. After three weeks' observation, pneumothorax was instituted on the left, with definite improvement. The temperature has been normal for more than two months. There is still slight cough but the sputum is only 4 to 20 c.c. daily in amount. The patient has gained in weight and has returned to school.

Dr. Wangensteen stated that a patient had recently been admitted for phrenic exeresis for bronchiectasis in whom Dr. Myers had already carried on pneumothorax compression for four years. The patient had been working consistently, but hoped that elevation and paralysis of the diaphragm would relieve her of a slight residual sputum.

Case 9.—A woman of 43 years was presented, who had cough and considerable sputum since the age of 38. There had been considerable weight loss and 175 to 240 c.c. of sputum was brought up daily. Exeresis of the phrenic nerve performed about two months ago had resulted in almost complete disappearance of sputum. There had been a persistence of slight cough, however, and recently the patient has been bringing up a little sputum. She returned to the chest clinic in the Out-patient Department of the University Hospital and was admitted to the hospital for her first neumothorax treatment, which she received today.

Dr. Wangensteen stated that it was gratifying to note the improvement in the patients with conservative types of treatment. He said that he had not done any complete deribbing operations as practiced by Hedblom in such cases, but stated that Dr. Kinsella and he had worked together on two cases of advanced bronchiectasis in which the conservative procedures of phrenectomy and pneumothorax followed by thoracoplasty over the lower left chest had been inffectual. They had then done the cautery lobectomy of Graham of the involved lung tissue in these two cases.

Dr. Wangensteen called attention to Dr. Graham's observation that many of the cases of bronchiectasis apparently follow infection of the paranasal sinuses. Alton Ochsner has been able to show that lipiodol placed in the nasopharynx is aspirated into the lung during sleep. The satisfactory eradication of sinus infection is therefore an important item in the treatment. In a number of cases of bronchiectasis in which repeated passive filling of the bronchi with lipiodol had been used, as suggested by Ochsner, definite improvement had been observed in only a few isolated instances.

In the next group of cases shown, surgery had been performed for pulmonary tuberculosis. Dr. Wangensteen stated that a demand had been created for this service by the superintendents of the tuberculosis sanatoria of the State, and that ten beds had been set aside at the University Hospital for the surgical treatment of such cases.

Case 10.—This young lady, aged 20, had been ill with pulmonary tuberculosis for two years. She had had bed rest at a sanatorium for fifteen months. She has recently maintained her weight and there has been only slight fever. The sputum is positive for tubercle bacilli and varies in amount up to 90 c.c. a day. X-ray examination reveals a large cavity in the lower left lobe. Unfortunately there is already a small cavity in the apex of the right lobe. Pneumothorax had been given on the left over a considerable period, since which time there had been definite improvement. The large cavities in the left lung were still open, however, owing to the presence of broad adhesions, and Dr. Wangensteen was of the opinion that a successful issue did not appear likely unless these could be effectually dealt with. The left diaphragm was not observed to move on fluoroscopy of the chest. The patient has a chronic proliferative type of disease for which compression by thoracoplasty is especially indicated. The small cavity in the apex of the right lung in all probability had its origin from the large ones on the left and if they can be sealed the lesion in the right lung may heal. An upper thoracoplasty in which paravertebral segments of the upper six ribs are removed subperiosteally has been done, and X-ray examination shows considerable diminution of size in the upper cavity. The air in the pleural cavity which would tend to interfere with the collapse was aspirated before the operative procedure. The patient had little reaction from the procedure and will be ready for the lower stage in a few days, at which time segments of the seventh to the eleventh ribs inclusive will be removed.

Dr. Wangensteen explained that it was important to cut the ribs as close to the spine as possible and that he exposed the articulations of the ribs with the transverse processes of the vertebræ, at which point they were divided. He felt that removal of wide segments of the upper two ribs was very important in obtaining collapse of apical cavities. With the arm pulled forward it was not difficult to sever the first rib as far proximally as the scalene tubercle. It has been pointed out by statistical studies from tuberculosis sanatoria that about 85 per cent of cases with persistent cavities are dead after three years. In event the small cavity on the right fails to heal, an apicolysis or excision of the three upper ribs should be done. In the experimental laboratory of the Department of Surgery at the University, Dr. Kinsella has done very extensive bilateral thoracoplasty in both dogs and monkeys, which procedures seem to be well borne. Bilateral pneumothorax in the treatment of tuberculosis has long been practiced.

Case 11.—The X-rays were demonstrated of a girl, aged 25 years, who had had pulmonary tuberculosis for eight years with large bilateral cavities, who was recently referred for thoracoplasty. There was evidence of spreading exudative tuberculosis in the base of one lung, also, and Dr. Myers and Dr. Wangensteen both felt that it was too late to do the patient any good. As in the case just demonstrated, so here the disease for a long time had probably been largely unilateral, at which time thoracoplasty would probably have been an effective remedy.

Case 12.—The X-ray films of a woman, aged 32 years, were shown who had a cavity that measured 11 × 13 centimeters in the left lung. The patient had been treated with pneumothorax and at one time it was believed that it was a large annular pneumothorax and not a cavity. The sputum level so nicely demonstrated in these films, taken in the standing posture, established the nature of the lesion. A phrenic exeresis followed by three-stage thoracoplasty had been done. After the typical two-stage paravertebral thoracoplasty, the anterior segments of the upper six ribs were also removed through an incision below the axilla between the pectoral and latissimus dorsi muscles. This large cavity was reduced to a cavity measuring 2 × 3 cm. in diameter, by these operative procedures. After the last operation, performed about 8 weeks ago, the patient was allowed to go home and she plans to return shortly for X-ray evidence of whether or not the cavity still persists. Persistence of the cavity is synonymous with continuance of the disease. In the event the cavity still persists, an apicolysis is indicated.

Case 13.—The next patient, a girl, 22 years of age, had had tuberculosis for six years. After bed rest for a few months she was well for two years, at which time a hemorrhage occurred. During the last three years she had been in bed continuously. Pneumothorax had been ineffectual because of adhesions. Upon admission to the hospital tubercle bacilli were found in the sputum which averaged about 60 c.c. daily. One large cavity and a few small cavities were visualized in the left upper lobe. A phrenic exeresis and a two-stage thoracoplasty had been done. When the patient left the hospital three months ago she had no sputum. She came in today for this presentation and for an X-ray examination. The latter shows a splendid collapse with complete obliteration of the cavities.

Case 14.—This patient, aged 50 years, had had tuberculosis for almost thirty years. Twenty-eight years ago he was given bed rest because of tuberculosis. His disease became arrested and he remained well until fourteen years ago, when a breakdown occurred. He had had sanatorium treatment for one year prior to admission. Pneumothorax failed because of adhesions and he was referred to the University Hospital for thoracoplasty. There was daily sputum of 50 to 75 c.c. which was consistently positive for tubercle bacilli. A phrenic exeresis and a two-stage thoracoplasty were done. The large cavity initially present in the upper left lobe had completely disappeared. There is evidence of considerable new bone regeneration from the periosteum of the ribs in these recent films. The patient has no sputum, has gained 28 pounds in weight and has worked steadily for more than a year.

The patients are urged to lie on sandbags as soon as they can tolerate them after the operation. This measure helps to increase the collapse. Dr. Wangensteen felt that better collapse is obtained with thoracoplasty on the left side, owing to the presence of the incompressible liver on the right. Reports from the literature would also indicate that operations on the left side are better tolerated.

Dr. Wangensteen stated that only 13 phrenicectomies without other subsequent compressive operative procedures for tuberculosis had been done at the University Hospital. He felt that phrenicectomy alone had a rather limited value in the treatment of pulmonary tuberculosis. In a rather large number of patients upon whom thoracoplasty was done, an initial phrenic exersis had been done. When the diaphragm was fixed, the improvement resulting from paralyzing it is not likely to be great, even though it may rise somewhat into the chest. Dr. Wangensteen said that, during the two or three-year period since this service had been established at the University Hospital, thoracoplasty had been performed upon 50 patients, representing somewhat more than 100 thoracoplastic operations. In this group there had been two operative deaths; one was an acromegalic with a tuberculosis of long standing with an extremely rigid chest who stopped breathing while the incision was being made. Attempts to resuscitate her proved futile. The other patient had an asthma in addition, from which she was rarely free. Seven ribs were removed and it was hoped that one operative procedure would suffice. An unstable mediastinum and the asthma proved too severe a handicap for her. A graded procedure in this instance would have been much wiser. There had been in addition three hospital deaths, viz., one from amyloid disease remotely after a three-stage thoracoplasty; one by suicide, and one from miliary tuberculosis. Though thoracoplasty appears to be a rather formidable type of operation, Dr. Wangensteen said that it was surprisingly well tolerated by these patients in rather frail health. The postoperative reaction in women he said was less then in men, owing to the presence of smaller ribs and muscles. In the unilateral chronic non-exudative type of tuberculosis with cavitation in which pneumothorax was of no avail, Dr. Wangensteen stated that thoracoplasty succeeded in returning to health and usefulness a rather large number of patients who would otherwise be resigned to incapacity and a lingering death. Dr. Wangensteen said that there had been a few deaths in his group after the patients had left the hospital, but that the operations were too recent to discuss the end-results.

He stated that Professor Bull, of Oslo, had stated in his introductory address at the Seventh International Conference on Tuberculosis, held in Oslo last summer, that 401 patients had had thoracoplasty performed in Norway since 1914. Of a group of 328 patients operated upon more than two years previously, Professor Bull said that 37.5 per cent had been restored to full activity, 13.4 per cent were considerably improved, and 41.8 per cent were dead.

Case 15.—The next patient shown, a girl aged 29, had exhibited an interesting diagnostic problem when admitted to the University Hospital. In the latter part of 1929 she had become ill with cough and pain in the left chest. She had had two small hemoptyses but there had been no sputum. She had been admitted to a sanatorium for the treatment of tuberculosis, but it was decided after a thorough study that she did not have tuberculosis. When admitted here, about eight weeks ago, she complained of severe pain in the left chest and anorexia. She presented an anemic appearance and the hemoglobin was found to be 60 per cent. The fever was of the septic variety, ranging as high as 102 degrees. There was a firm brawny tender mass over the left chest wall involving the breast. There were no sinuses or fistulæ; the skin was a deep brown over the area of induration. An X-ray of the chest showed a mass within the chest as well; a lateral film showed it to be in the anterior portion of the chest. There was slight thickening along the margins of the ribs. Aspiration of the pleural cavity before admission had repeatedly been negative. A lipiodol filling of the bronchi was done and antero-posterior and lateral films were again made. The lung was apparently displaced into the posterior mediastinum by the mass. Two diagnostic impressions were entertained: (1) actinomycosis and (2) endothelioma of the pleura with invasion of the chest wall. It was believed that aspiration of the indurated area in the breast with a large needle and syringe suction would aid in the diagnosis by revealing either sulphur granules or small pieces of tissue which could be embedded in paraffin. After infiltrating the skin with novocaine, a large needle was pushed through the healthy skin beneath the breast and several cubic centimeters of sanguineous fluid was obtained in which scores of tiny sulphur bodies were present. The ray fungus was easily demonstrated by squeezing one of the sulphur bodies between a glass slide and a cover-slip in a drop of water. A paraffin block was made from the sediment and a large number of colonies were seen in the stained section. Dr. Wangensteen remarked that the tissue diagnosis of actinomycosis often established the diagnosis when the organisms could not be demonstrated in the fresh exudate. He said that the physician who makes the first puncture has the best chance to make the diagnosis and related that he had once aspirated a lesion in the cheek and observed the sulphur granules. The next morning when he repeated the procedure before his class he was chagrined in failing to demonstrate their presence. Decompression of the lesion permits the exudate to escape, after which the colonies of actinomyces are not easily demonstrated. In such cases when actinomycosis is suggested, Dr. Wangensteen felt that the tissue diagnosis should be depended upon.

A semilunar incision was made beneath the breast and the latter turned upward. Considerable seropurulent exudate came away, in which myriads of sulphur bodies were still present. The anterior segments of the third, fourth and fifth ribs were excised together with a portion of the pleura. The granulomatous type of tissue present was extremely vascular and there was considerable bleeding which was easily controlled by packing. Since the patient was operated upon there has been considerable reduction in fever and the pain in the left chest has disappeared. The appetite is good. The wound in the left chest has healed, but a lateral plate still shows the lung displaced posteriorly and Dr. Wangensteen felt that the patient should be re-operated upon in an attempt to excavate fairly completely the granulomatous tissue. The patient had been on large doses of iodides (5 to 10 grams daily). No X-ray treatment had been employed in this case. Dr. Wangensteen felt that radical excision, combined with the provision for escape of exudate by drainage, was the essential in the treatment. Two previous cases of thoracic actinomycosis that had extended from an uncontrolled cervical actinomycosis had proven refractory to X-ray and radium and both patients died.

The histories and X-ray films of two patients that had been treated for suppurative disease of the lung and pleura, but who proved to have carcinoma of the lung at autopsy, were briefly reviewed.

Case 16.—This patient was a man of 49 who had been ill with pneumonia in February, 1930. In May, he was operated upon for empyema and again in August. In October, 1930, he was admitted to the University Hospital with a weight loss of 70 pounds and an anemia (hemoglobin 60 per cent). There was considerable sputum and also drainage from a sinus in the left chest. An X-ray film demonstrated a dense shadow filling the entire left chest. There was relatively little drainage from the sinus in the chest compared with the amount of sputum. Bronchoscopy was negative. It was felt, therefore, that an abscess of the lung was the primary condition and an external drainage was performed just lateral to the heart. A carnified lung was found and pus obtained. The patient's condition imroved but he still continued to have fever and sweats. Ie also had some difficulty in swallowing. At a second peration about three weeks later an attempt was made o open up the old sinus in the chest more widely. As oon as the skin was incised there was a brisk venous emorrhage without apparent cause. For the first time t was suspected that the patient might have malignancy. 'his wound continued to bleed occasionally despite ather tight packing and the patient continued to fail nd died about three weeks after the last operative rocedure.

Autopsy showed a diffuse carcinoma of the entire ıng with encirclement of the lower esophagus. A ırge benign nephroma was also present in the left idney.

Case 17.—A man of 66 had been taken ill with cough nd fever in June, 1930. There was rusty sputum of bout a week's duration, after which there was sub- idence of the fever and the patient returned to work. Ie did not feel quite well all summer and lost a few ounds in weight despite a good appetite. In Septem- er he had periodic chills and fever and a slight un- roductive cough. In October, 1930, he was admitted the University Hospital. Examination showed a ırge man with some pallor and evidence of wasting. Iis temperature ran as high as 101° F. daily; physical xamination otherwise was essentially negative. X-ray xamination disclosed an almost perfectly spherical ıass about the size of a tennis ball to the right of the eart and in the anterior mediastinum as seen on the ıteral film. Bronchoscopic examination was negative. 'he contour and location of the homogeneously dense rea suggested very strongly a dermoid cyst. The ıass was definitely in the lung and was not thought be a circumscribed Hodgkin's of the lung. Because f the infectious features in the history it was felt best approach the lesion as though it were an encap- ılated empyema or an abscess. During the week that receded the operation the patient felt that he was aining rapidly. At operation, performed under local nesthesia, the anterior segments of the second, third, nd fourth ribs were removed. A free pleural space 'as encountered and an iodoform gauze pack was left n the pleura. A week later the wound was reopened, ıd the mass was needled through the pleura. Pus was btained and the pleura was incised and a drainage act was made into the lung with the endotherm knife. Vhen the mass was reached more exudate in which eces of tissue were clearly visible came away. It was bvious, therefore, that the lesion was a malignant ımor that had broken down. Microscopic examination f the tissue showed adenocarcinoma.

The next morning without warning or obvious cause ıe patient became suddenly extremely dyspneic. xygen afforded only slight relief. Shock quickly ıpervened and before the patient could be transfused expired.

Autopsy showed a large carcinoma of the hilum of ıe right lung with a large fist-sized tumor mass plug- ng the right atrium and extending through the mitral ılve into the left ventricle. The extension of the ımor by way of the pulmonary vein directly into the heart served as a satisfactory explanation for the sudden dyspnea and shock. The not infrequent complication of brain abscess in pulmonary suppuration of various types, Dr. Wangensteen said, had its explanation in this mode of spread. Such abscesses occur in the left cerebral hemisphere, he said, in about 75 per cent of instances.

Dr. Wangensteen commented on the difficulties of making an early diagnosis of carcinoma of the lung and on the several sources for confusion. He believed that there are no early symptoms on which the diagnosis can be made with assurance. Reliable bronchoscopic examination and X-ray films, together with a critical analysis of the history, he felt, were of most value. Unfortunately the treatment of carcinoma of the lung is as unsatisfactory as its recognition. Most primary carcinomas of the lung begin in the main bronchi; a lesser number start in the parenchyma. These latter tumors should be amenable to surgical excision (lobectomy) or destruction with the cautery. Professor Sauerbruch had obtained 3- to 5-year cures in the bronchi is early recognition by bronscopy and hope of dealing satisfactorily with the more numerous group of primary carcinomas of the lung that originate in the chonchi is early recognition by bronchoscopy and endoscopic treatment with radium and diathermy. Kernan, of New York City, Dr. Wangensteen said, has reported such a case in which the tumor completely disappeared under such treatment. The symptomatology, diagnosis, and treatment of carcinoma of the lung all need intensive study and clarification.

Dr. E. K. Green made a motion that a vote of thanks be given the Surgical Staff and Superintendent for the fine program which had been presented, and for the dinner preceding the program.

Dr. A. T. Mann said that personally he felt as though he had been at a rather full program of the Tri-State and also expressed the thanks of the Surgical Society.

Dr. Wangensteen replied that it had been a pleasure to have the opportunity of entertaining the Society in this way.

H. O. McPheeters, M.D.,
Secretary.

ZINC CHLORIDE IN CANCER

The use of zinc chloride and similar caustics in the treatment of cancer has been practically abandoned by all except the "cancer cure" quacks. Such caustics are difficult of control, so that there is destruction of healthy, as well as of malignant, tissue; their action is slow, thus unnecessarily prolonging the pain of removal. Much better results can be obtained by the judicious use of surgery when the growth is operable, or by the use of radium and roentgen rays when the disease has advanced beyond the chance of its complete removal. The use of such caustics has been abandoned also by the progressive dermatologists in the treatment of small epitheliomas of low malignancy; they use, instead, radium, roentgen rays, or coagulation with high frequency currents. (Jour. A. M. A., March 7, 1931, p. 797.)

PROGRESS

Abstracts to be submitted to Section Supervisors.

Members are urged to abstract valuable articles which they run across in their reading and send the abstracts to the physicians in charge of the respective sections. In order to avoid duplication it would be well to communicate with one of the section supervisors before the article is abstracted.

TUBERCULOSIS ABSTRACTS*

When as a young man Sir Robert Philip, now professor of tuberculosis in the University of Edinburgh, announced his intention of specializing in tuberculosis, one of his wisest and kindest teachers said, "Don't think of such a thing. Phthisis is worn to a very thin thread. The subject is exhausted." Fifty years of untiring labor and leadership have dimmed neither the zest nor the perceptions of this pioneer. Recently, Sir Robert delivered the Malcolm Morris Memorial Lecture on "The Outlook on Tuberculosis." After reviewing the past, he sounded the call for fresh orientation. Advanced disease of the lung, he said, has absorbed most of our interest in the past; it is time to shift attention more and more towards the earliest indications of tuberculosis infection. In this number of "Tuberculosis Abstracts," there is space only for comment on this phase of tuberculosis control. Sir Robert Philip's interesting and comprehensive monograph was published in the British Medical Journal of January 10, 1931.

Determining Earliest Indications of Infection

Pulmonary tuberculosis is in reality a late, visceral manifestation of an infection contracted much earlier. The author has had opportunity in numerous instances to trace the development of tuberculosis in the same subject in ever-changing form from the seed stage up to full fruition; in some instances, for 30 years or more. The ebb and flow—the arrest and advance of the disease—are but expressions of the continuing contest between the invading organism and the resistance of the tissues of its host. While the invading organism is presumably little changed save in respect of numbers, the resistance offered varies endlessly as a result of intercurrent illness; accident, strain, and a host of environmental influences. Infection is the crossing of the frontier—the beginning of what is often a lifetime contest.

SCIENTIFIC ANTICIPATION

The hope of preventing the endless possibilities of subsequent mischief following infection led the author some years ago to recommend the systematic examination of contacts. The next step was to advise the search for the earliest traces of tuberculous infection in every child. As infection takes place most commonly during childhood, the tuberculin test, he believed, should become routine practice at stated intervals from early infancy onward. So long as the reaction remains negative, nothing further is necessary. Whenever a positive reaction is obtained for the first time, the fact and the date should be recorded on the permanent medical history of the child.

If, after positive determination, the health of the child continues thoroughly good, we have the knowledge that the child's resistance is sufficient, and there is no call for treatment. On the other hand, the positive determination may illuminate many after-events. Vague conditions of "delicacy" in the child may find their explanation—for example, malnutrition, obscure feverish attacks, ill-defined lack of energy, so-called "disturbed action of the heart," which may interfere with the claims of education and sport. Such conditions are very frequently the expression of tuberculous infection. Further, the occurrence of incidental illnesses, such as measles and whooping-cough, will call for watchfulness, and care will be taken to secure complete convalescence after such attacks. The doctor will insist on the maintenance of a high level of resistance, more particularly in relation to school life, the period of adolescence, and the time of entrance into more responsible life.

---

DETERMINE THE FACT AND DATE

Preventive medicine may wisely take a lesson from the sphere of agriculture. The practical farmer who seeks to raise a tubercle-free herd has learned the value of the tuberculin test. A method for the early detection of tubercle which is worth the farmer's while on economic grounds has still greater significance and wider efficacy—both medically and economically—in dealing with the human race.

Sir Robert Philip would not make a formal distinction between reactors and non-reactors but recommends the routine practice of determining the *fact* and *date* of the initial infection in every child. That is a service which might well commend itself to the American physician, who is growing increasingly interested in preventive medicine and strives to render to his families a positive health service.—*The Outlook on Tuberculosis: Changing Orientation, Sir Robert Philip, The British Med. Jour., Jan. 10, 1931.*

PAPER STIMULATED WIDE INTEREST

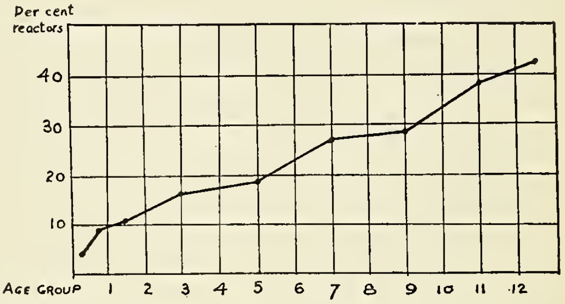
Sir Robert's paper immediately stimulated much discussion among the medical profession of England and Scotland. The comments were, on the whole, favorable, and reflected the deep respect which is felt by doctors and laymen for the genius and leadership of the author. To him, said one writer, is due almost entirely the present favorable position of the campaign against tuberculosis. The comments, together with Sir Robert's final rebuttal, were printed in subsequent issues of the *British Medical Journal.* Some of these are briefly abstracted below.

Robert Carswell raised this question: Supposing the fact and date of tuberculization has been duly noted in relation to each child; what practical use is now to be made of the information? Excluding specific methods of immunization or "detuberculization," Sir Robert Philip's answer, he says, is too nebulous. He believes that a more definite attempt should be made to immunize the child (presumably by some form of vaccination). In spite of many failures, there has been sufficient success with preventive immunization, supported by ordinary hygienic measures, to make it more than a hope, and he submits that demonstration to prove the value of detuberculization is the next most important step in the campaign against tuberculosis.

TEST A CLUE TO SOURCE OF INFECTION

John Gibbens takes issue with that part of the essay which implies that malnutrition, obscure feverish attacks, lack of energy, and the like may be the expression of tuberculous infection in a child who reacts positively to the tuberculin test. Tuberculosis carries with it too great a stigma to justify anyone in diagnosing it easily in such delicate children. The value of the positive Mantoux test, he says, lies rather in stimulating the doctor to get the child back to full health as rapidly as possible. Gibbens admits that knowledge of the fact of tuberculization is extremely important but for another reason; namely, that the earlier the age at which a positive reaction is found, the more likely is one to find the adult that is disseminating the infection.

W. Camac Wilkinson emphasized that the environment of the child is the source of infection. Too much attention cannot be paid to the environment of the child if we wish to tackle infection at its source. "Neither fresh air nor sunshine can prevent tuberculosis in children living in the houses of consumptive parents."—*The British Med. Jour., Jan. 24, 1931.*



Mantoux Reactions of 1,286 Children—Bellevue Hospital, New York, from 1921 to 1928. (From Tuberculin Skin Reactions, C. H. Smith, Am. Jour. Dis. of Children, Dec., 1929.)

Sir Robert Philip in his answer disclaims responsibility for misunderstandings voiced and reiterates that to the question, "Have we reached finality?" an emphatic negative must be given. He repeats his plea for the systematic search for, and determination of the fact and date of initial infection in every child, primarily so that the information may be kept in view throughout the further life-history of the individual in order that, if indications of progressive tuberculization supervene, they may timeously be met by measures of detuberculization.—*The British Med. Jour., Feb. 7, 1931.*

THE EFFECT OF LESSENED RESPIRATORY RESERVE ON BLOOD AND CIRCULATION: Willis S. Lemon (Arch. Int. Med., Vol. 45, No. 1). This study deals with the effects produced on the respiratory reserve by lessened mechanical efficiency, and an attempt to discover the point at which reserve is lost, at which respiration, as a function, is inadequate, and at which circulatory aid is required so that an animal can maintain a comfortable existence.

Avulsion of all intercostal nerves on left side of dog was performed ten days later; the same thing was done on right side. One week later, phrenic neurectomy was performed on right side. Five days after, a left phrenic neurectomy was performed. Breathing was now dependent on extra-respiratory muscles in neck and shoulders, and to muscles attached to ribs on the vertebral side of the operative sites.

The behavior of the dog was similar in respects to other dogs which were normal. It could not, however, respond to vigorous exercise with the same ease because the vital capacity was lessened. The animal was thus still capable of ordinary activities, and with the ability to develop a vital capacity in excess of tidal air requirements.

The introduction of phrenic neurectomy does not alter in any way the movement of the chest wall. Asymmetry and reduction of outward lateral movement occur when the intercostal nerves on one side are sectioned. The reduction of movement amounts to from 30 to 50 per cent of normal, depending on the number sectioned. Symmetry and bilateral reduction of movement result in bilateral section of the intercostal nerves.

The dog was allowed to live under normal conditions and surroundings for one year. He developed normally and did not experience any difficulty either in urination or defecation, despite paralysis of the whole diaphragm and of the upper abdominal muscles. The muscles of the lower abdomen underwent hypertrophy. Respiratory movements were normal, and he was dyspneic only after unusual exertion. He could run up and down stairs without embarrassment.

One year after the last previous operation, abdominal cavity was opened and diaphragm was resected from its ventral attachment. It was noted that whole diaphragm had taken a position high in the thorax and atrophy was so excessive that the muscular portion could not be distinguished from the tendinous portion, except with difficulty, and whole diaphragm so thin that lungs were plainly visible through it. The dog now learned to breath differently, the chest raised as one piece during inspiration, and at the same time the abdomen contracted strongly.

The three functions of the diaphragm—respiratory, pressure-producing, and partition-effecting—were almost completely destroyed.

Ten months later, the abdominal cavity was again opened. The stomach, duodenum, and all but two lobes of the liver had forced their way into the thorax. The diaphragm was detached from side to side, and backward as far as possible. After recovery from the operation, the dog was healthy and active and did not show any evidence of respiratory embarrassment.

The studies showed: 1. Vital capacity was lessened, but never beyond the point where it failed to be equivalent to tidal air. The ventilation in liters of air breathed each minute reached a high normal amount, but was not distinctly abnormal at any time.

2. The hemoglobin decreased from high to low normal percentages, but the normal amount of hemoglobin for each 100 c.c. of blood was within normal limits.

3. The number of erythrocytes failed to indicate either temporary or permanent erythrocytosis, such as might have been anticipated had respiratory competence been destroyed.

4. The arterial and venous oxygen content and the oxygen of the blood were essentially normal.

5. The heart remained normal functionally, and has not shown evidence of hypertrophy, and the electrocardiogram cannot be interpreted as evidence to indicate any definite failure of the right ventricle.

The experiment illustrates the degree to which muscular dysfunction may be carried before respiratory incompetence develops in an animal which has normal heart and lungs. It seems to confirm the independence of two fundamental functions having interrelated duties; great loss of reserve in one is required before demonstrable evidence of coöperative support is provided by the other.

E. T. Johnson.

NON-APICAL INFILTRATIONS IN PULMONARY TUBERCULOSIS. Karl Fischel (Amer. Rev. of Tuberc., 1931, XXIII, 139). To diagnose pulmonary tuberculosis in its earliest stages we must locate the lesion in many instances before symptoms appear and even before physical signs can be detected. The small centrally located focus may be active and spreading while the patient is apparently in good health. Assman was one of the first to report such foci in the infraclavicular area. Serial X-ray films make their identification possible. Redeker and others have shown that pulmonary tuberculosis usually begins in this manner and that tuberculosis limited to the apex is a comparatively late manfestation of the disease and is frequently evidence of a conflict already won while isolated lesions lower down have a much graver significance. Their views have been confirmed by various German, English and American writers.

Fischel discusses the relation of these lesions to Ranke's theory which recognizes three stages in tuberculosis. Ranke's primary complex is now generally known in this country as the primary or childhood type of tuberculosis and includes the primary Ghon lesion and the enlarged regional lymph glands which accompany it. It is predominantly a tuberculous lymph adeitis. This primary lesion of tuberculosis is accompanied by a profound, modification of all the tissues of the body (allergy) so that they are hypersensitive to the tubercle bacillus and its products.

Ranke's second stage begins with the first reinoculation of the allergic animal body. Inflammatory changes consisting of hyperemia, edema, emigration of leukocytes, etc., make up the anatomical picture of the focus of reinfection. The early non-apical infiltrations which Fischel considers the usual beginning of serious pulmonary tuberculosis in adults are accompanied by the inflammatory changes characteristic of a second infection with tubercle bacilli of tissues made hypersensitive by a previous infection somewhere in the body.

We are really dealing with an acute bronchopneumonia surrounded by an area of perifocal inflammation and in no way walled off from the surrounding tissue. It has free communication through the bronchi, blood vessels and lymphatics with other parts of the body. The fate of the patient at this critical period depends on the stabilization of his immunity. If he is not overwhelmed by his extrẽme hypersensitiveness, the lesion may quickly heal and disappear, providing the patient is given prompt treatment. In many cases if he becomes toxic and the lesion is apparently spreading rapidly, producing caseation and cavities, immediate pneumothorax will often turn the balance in the patient's favor and save his life.

Fischel believes the proper interpretation of the lesions found in so-called apical tuberculosis is that they are the late results of favorable cases. Fairly extensive subapical lesions have eventually involved the apices. Retrogression and healing have been slower there and changes may persist after the lesion below the clavicle or in the middle field have disappeared. As far as X-ray and physical signs are concerned, any lesion in the subclavicular region will tend to diminish the elasticity of the lung above.

The importance of frequent X-ray examinations of exposed individuals and the most prompt and careful hospital study of suspected cases are emphasized.

A. T. Laird.

CASES OF PULMONARY TUBERCULOSIS WITH EARLY CAVITY FORMATION AND FEW SYMPTOMS (Tuberculoses torpides cavitaires d' emble'e). E. Buc (Revue de la Tuberculose, 1930, X, 1096). "In certain cases one finds completely softened tubercles in the midst of crepitant lung tissue, and in these cases the walls of the cavities are smooth and seem to be formed only by lung tissue a little compressed or thickened but without any trace of a false membrane." So wrote Laennec, nearly a hundred years ago.

Buc states that cavities are not always the result of the breaking down of large caseous foci and claims that they may appear very quickly, even in a few days, at the very start of a rapidly developing tuberculosis; in fact they are often the first demonstrable lesions in cases that eventually become chronic. Without doubt from an anatomic point of view, the loss of substance is caused by the breaking down of a small caseous area, but this produces practically no clinical phenomena.

The cavity is almost always an unexpected discovery during an X-ray examination. As noted above, very few symptoms accompany its formation. There may be a persistent cough which annoys the patient or a small amount of sputum which is very viscid. Sometimes this expectoration is present at the very beginning; in other cases it is preceded by a few acute symptoms, a slight hemoptysis, or a febrile attack lasting a few days, or loss of weight and strength may be noted.

These symptoms are likewise often of very recent origin and have been present only a few weeks before the X-ray shows a cavity about which there can be no doubt, of considerable size. At this time the cavity is the principal lesion seen, it is isolated and solitary. The broncho-vascular trunks may appear thickened but the parenchyma appears practically normal. Consecutive films show the formation and increase in size of such cavities. At first their contours may be faint and indistinct, while the surrounding tissue is not much different from the normal lung. This is Jacquerod's first stage of cavity formation. In other cases although symptoms have lasted only a few weeks the cavity is already large, with definite borders and it is surrounded by an area of lessened density. One might think the cavity was much older than the history of the case would lead one to suppose. It is impossible to say from the film how long the cavity has existed, but there can be no doubt that it may appear without preceding consolidation of any great extent.

Outside of X-ray study, sputum examination is the most useful diagnostic procedure in these cases. The amount of sputum is usually very slight and patients may even say they do not expectorate; others will admit that they occasionally expectorate a small amount. Sometimes examination of feces will give positive results. When the cavity is present and enlarging, tubercle bacilli are usually found in spite of the paucity of symptoms. The syndrome really consists of three elements: X-ray evidence of cavity, positive sputum and comparatively good general condition. Cavities may persist unchanged even for an entire year or more. Increase in weight may mislead one as to the seriousness of the condition. The spontaneous disappearance of such cavities is much less rare than is the case with other cavities due to tuberculosis. Often no trace remains. Of twelve cases, six underwent spontaneous cure under sanatorium care. Symphisis of the pleura seems to occur rather frequently in cases with cavities of the type under consideration. Artificial pneumothorax and phrenicectomy are valuable when there is no tendency to spontaneous disappearance, but they are not employed until a period of observation of several months at the sanatorium has demonstrated that no such tendency is present. In suitable cases they are most valuable, as they are followed by rapid disappearance of tubercle bacilli from the sputum. This is very important, since often on account of the appearance of good health and freedom from symptoms these patients are very dangerous to those who live with them.

A. T. Laird.

PEDIATRICS

TUBERCULOSIS.. Allergic, anaphylactic and immune reactions in guinea pigs following inoculations with heat-killed tubercle bacilli. A. Branch and H. R. Cuff (Jour. Infect. Dis., 47:151, Aug., 1930). Branch and Cuff found injections of heat-killed virulent tubercle bacilli, when given in sufficient dosage and concentration by intraperitoneal, intrapleural, intratesticular or subcutaneous routes in guinea pigs, to set up a state of allergy in the inoculated animal, as evidenced by positive intracutaneous and testicular reactions to old tuberculin and by positive Pfeiffer phenomena when living virulent organisms are injected. The most rapid and intense reactions follow intratesticular inoculations. The least constant and slightest reaction is elicited by subcutaneous inoculations. Failure to develop allergy was noted following intracardiac, intravenous and intramuscular administration of doses of three to five mg. The development of allergy following injections of heat-killed virulent tubercule bacilli thus varies considerably, depending on where the dose is administered. Allergy may develop in fifteen days of inoculation with three mg. of heat-killed tubercle bacilli in the peritoneum or pleura, but in their experimental animals anaphylaxis did not appear until at least three weeks after the inoculations. They feel, therefore, that allergy and anaphylaxis are not directly related. Furthermore, allergy is a phenomenon distinct not only from immunity but also from anaphylaxis as shown by the fact that some intramuscularly inoculated guinea pigs that are non-allergic to old tuberculin, yet develop typical lethal shock when old tuberculin is inoculated directly into the blood stream; allergic guinea pigs may show anaphylaxis but not always.

In general Branch and Cuff conclude that allergy and anaphylaxis in tuberculosis are independent phenomena, and that immunity may be present without allergy. In addition intramuscular (and probably intravascular) injections of heat-killed tubercle bacilli produce immunity and anaphylaxis without allergy, whereas intraperitoneal, and intrapleural injections produce all three of the above conditions. They feel that the practicability of prophylactic immunization of children by intramuscular inoculations with heat-killed virulent bacilli is suggested, the advantage being that if immunity can be obtained without allergy, the valuable tuberculin skin test, if later positive, is evidence of reinfection and not the result of vaccination.

C. A. Stewart, M.D.

SURGERY

THE CONSERVATIVE TREATMENT OF PREPATELLAR BURSITIS. Louis Carp (Surg., Gynec. & Obstet., January, 1931, Vol. 52, pp. 87-91). Twenty-seven consecutive cases of acute or chronic prepatellar bursitis were studied to determine the end-results of conservative therapy. The technic consisted of evacuating the fluid as comppletely as possible and injecting 2 to 5 c.c. of 3.5% tincture of iodine into the bursa. The needle was withdrawn and the skin over the bursa massaged vigorously. The knee was placed in complete extension and a pressure bandage applied. In 60 per cent of the cases small amounts of fluid re-accumulated. Aspiration of this fluid was employed; a second injection of the tincture of iodine usually was not necessary. Twenty-four cases were followed an average of 16 months and showed no symptoms or reappearance of the bursal fluid.

Herbert A. Carlson, M.D.

NEW AND NON-OFFICIAL REMEDIES

TRUTH ABOUT MEDICINES

Pollen Extracts-Arlco.—The following pollen extracts-Arlco (New and Nonofficial Remedies, 1930, p. 29) have been accepted: Birch Mixture Pollen Extract-Arlco; Maple Mixture Pollen Extract-Arlco; Oak Mixture Pollen Extract-Arlco. Arlington Chemical Co., Yonkers, N. Y. (Jour. A. M. A., March 7, 1931, p. 773.)

Iopax.—Sodium 2 - oxo - 5 - iodopyridine - N - acetate, Iopax contains from 42 to 43.5 per cent iodine. It is proposed for use intravenously in radiographic visualization of the urinary tract. It is also used for injection into the renal pelvis through the ureteral catheter for pyelography. The maximum intravenous dose is 30 Gm. of the powder dissolved in 100 c.c. of redistilled water. Schering Corporation, New York. (Jour. A. M. A., March 14, 1931, p. 859.)

Nupercaine-Ciba.—a-butyloxycinchoninic acid, Υ-diethylethylenediamide hydrochloride. Nupercaine was first introduced as percaine. Nupercaine is a local anesthetic, acting like cocaine when applied to mucous surfaces and like procaine or cocaine when injected, the action being relatively prolonged. Nupercaine is about five times as toxic as cocaine when it is injected intravenously into animals, and its anesthetic activity is correspondingly greater than that of cocaine when it is applied to a mucous surface; it is many times more active than procaine hydrochloride when it is injected subcutaneously. It is reported to have caused necrosis of tissue in one case and a condition resembling gangrene with recovery in another. Death has been reported after the subcutaneous injection of 135 c.c. of a solution of 1 in 1,000. The usual precautions should be observed when it is injected into the spinal canal or into the urethra. Nupercaine is supplied in the form of crystals; ampules buffered solution 2 c.c., 1:200; ampules solution 5 c.c.; 1:1,000; solution 2 per cent, and tablets, 0.05 Gm. Ciba Company, Inc., New York. (Jour. A. M. A., March 21, 1931, p. 946.)

Schick Test.—A diphtheria immunity test (New and Non-official Remedies, 1930, p. 380) marketed in packages of one capillary tube containing undiluted diphtheria toxin standardized, sufficient for ten tests, accompanied by sterile diluent; in packages of one capillary tube containing undiluted diphtheria toxin standardized, sufficient for fifty tests, accompanied by sterile diluent; in packages of two capillary tubes containing undiluted diphtheria toxin standardized, sufficient for one hundred tests, accompanied by sterile diluent. As a means of control the Schick test control is supplied. National Drug Co., Philadelphia.

Ephedrine Hydrochloride-Gane and Ingram. — A brand of ephedrine hydrochloride-N.N.R. (New and Non-official Remedies, 1930, p. 168). Gane and Ingram, Inc., New York.

Ephedrine Sulphate-Gane and Ingram.—A brand of ephedrine sulphate-N.N.R. (New and Non-official Remedies, 1930, p. 170). Gane and Ingram, Inc., New York.

Tuberculin Old (Human).—Tuberculin-Koch (New and Non-official Remedies, 1930, p. 358) marketed in single 1 c.c. vial packages; also in packages of one 4 c.c. vial. National Drug Co., Philadelphia. (Jour. A. M. A., January 3, 1931, p. 39.)

Pollen Extracts-Cutter.—The following pollen extracts-Cutter (New and Non-official Remedies, 1930, p. 31) have been accepted: Oak Pollen Extract-Cutter; Western Ragweed Pollen Extract-Cutter; Western Water Hemp Pollen Extract-Cutter. Cutter Laboratory, Berkeley, Calif.

Winthrop Viosterol in Oil 250 D.—A brand of viosterol in oil 250 D-N.N.R. (New and Non-official Remedies, 1930, p. 410; Jour. A. M. A., October 4, 1930, p. 1021). Winthrop Chemical Co., Inc., New York. (Jour. A. M. A., January 24, 1931, p. 271.)

Tetanus Gas Gangrene Antitoxin (Lederle) Refined and Concentrated.—An anaërobic antitoxin (New and Non-official Remedies, 1930, p. 343) prepared by immunizing horses with gradually increasing doses of the toxins of *B. tetani, B. perfringens,* and Vibrion septique. The toxins are individually prepared. The product is marketed in packages of one syringe containing one prophylactic dose, stated to represent tetanus antitoxin 1,500 units, perfringens antitoxin 1,000 units and Vibrion septique antitoxin 10 units. Lederle Laboratories, Inc., Pearl River, N. Y.

Gas-Gangrene Antitoxin (Polyvalent) Refined and Concentrated, Without Tetanus Antitoxin.—An anaërobic antitoxin (New and Non-official Remedies, 1930, p. 343) prepared by immunizing horses with subcutaneous injections of gradually increased doses of the toxins of *B. perfringens,* Vibrion septique, *B. oedematiens, B. sordelli and B. histolyticus.* The toxins are individually prepared. The product is marketed in vials containing one minimum therapeutic dose, stated to represent perfringens antitoxin 10,000 units, Vibrion septique antitoxin 100 units, *B. oedematiens* antitoxin 200 units, *B. sordelli* antitoxin 200 units, and *B. histolyticus* antitoxin 25 units. Lederle Laboratories, Inc., Pearl River, N. Y.

Tablets Amytal, ¾ grain.—Each tablet contains amytal (Jour. A. M. A., October 18, 1930, p. 1178), ¾ grain. Eli Lilly & Co., Indianapolis.

Ampules Gold Sodium Thiosulphate-Abbott, 0.01 Gm.—Each ampule contains gold sodium thiosulphate-Abbott (Jour. A. M. A., December 20, 1930, p. 1913), 0.01 Gm. Abbott Laboratories, North Chicago, Ill.

Sulpharsphenamine-Metz, 0.75 Gm. Ampules.—Each ampule contains sulpharsphenamine-Metz (New and Non-official Remedies, 1930, p. 72), 0.75 Gm. H. A. Metz Laboratories, Inc., New York.

Sulpharsphenamine-Metz, 0.9 Gm. Ampules.—Each ampule contains sulpharsphenamine-Metz (New and Non-official Remedies, 1930, p. 72), 0.9 Gm. H. A. Metz Laboratories, Inc., New York.

Sulpharsphenamine-Metz, 3.0 Gm. Ampules.—Each ampule contains sulpharsphenamine-Metz (New and Non-official Remedies, 1930, p. 72), 3.0 Gm. H. A. Metz Laboratories, Inc., New York. (Jour. A. M. A., January 31, 1931, p. 357.)

Diphtheria Toxoid.—This product (New and Non-official Remedies, 1930, p. 365) is also marketed in packages of five immunization treatments, in packages of fifty immunization treatments. For the two dose method of treatment the following forms are marketed: packages of one immunization treatment; packages of five immunization treatments; packages of ten immunization treatments, consisting of one vial; packages of fifteen immunization treatments, consisting of one vial; packages of fifteen immunization treatments consisting of thirty vials; in packages of fifty immunization treatments, consisting of one hundred vials. The National Drug Co., Philadelphia.

BOOK REVIEWS

Books listed here become the property of the Ramsey and Hennepin County Medical libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

BOOKS RECEIVED FOR REVIEW

HEART DISEASE. Paul Dudley White, M.D., Instructor in Medicine, Harvard Medical School; physician, Massachusetts General Hospital, Boston. 931 pages. Illus. Price: $12.00. New York: The MacMillan Company, 1931.

FUNDAMENTALS OF DERMATOLOGY. Alfred Schalek, M.D. Professor of Dermatology and Syphilology, University of Nebraska, Rush College, etc. 247 pages. Illus. Price: $3.00. Cloth. Philadelphia: Lea & Febiger, 1931.

TREATMENT OF INJURY BY THE GENERAL PRACTITIONER. Clay Ray Murray, M.D., F.A.C.S. Assistant Professor of Surgery, College of Physicians and Surgeons, Columbia University, etc. 2 Vols. 412 pages. Illus. Price: $5.00, flexible binding. New York: Harper & Brothers, 1931.

HANDBOOK OF ANATOMY, BEING A COMPLETE COMPEND OF ANATOMY. James K. Young. Revised by George W. Miller. 7th rev. ed., with 154 engraving, some in colors. Philadelphia, F. A. Davis Co., 1930.

This book is leather bound and the printing is clear and large so that it is easily read. There are 426 pages and 154 diagrams and plates. The purpose of this book as stated in the preface is "to lighten the labor of the student of medicine," and I believe that the book accomplishes that purpose. The book is clear, brief, and concise. Tables and diagrams are utilized to fix the different systems in the student's mind. The book is complete in every department and because of its conciseness is a valuable reference book.

A. N. BESSESEN, JR., M.D.

CLINICAL ALLERGY, PARTICULARLY ASTHMA AND HAY FEVER: MECHANISM AND TREATMENT. Francis M. Rachemann, M.D. 588 Pages and 30 Illustrations. Price $10.50. New York: The MacMillan Co.

During the past fifteen years the increasing interest in the allergic diseases has resulted in the formation of clinics and special societies for its study and individuals have also recorded their numerous observations. From this work has come a vast amount of literature on the subject in all its phases, some of it controversial or contradictory but much of it fairly well proven at the present time and forming the foundation on which our present knowledge of allergic conditions rests.

In this monograph the author, with great patience and much hard work, has reviewed the entire literature and has interpreted it, without bias, in the light of his own clinical experience at the Massachusetts General Hospital. The subject matter is very well arranged, and ably and fully presented. The first half of the book, covering the phenomenon of hypersensitiveness, explains the various theories of its nature and origin recognized at the present time. There are several excellent chapters on vaccine therapy and the mechanism of the tuberculin test. The second half of the book is devoted to the diagnosis and treatment of the various allergic diseases, especially hay fever and asthma.

This monograph is without question the most complete, thorough and modern of the various works on allergy. Anyone interested in the subject will find in it much food for thought as well as many valuable suggestions for the diagnosis and treatment of conditions which are usually puzzling. The bibliography is most complete and valuable for reference purposes.

E. V. Kenefick, M.D.

MENTAL ASPECTS OF STAMMERING. C. S. Bluemel, M.A., M.D. Clinical Instructor in Neurology at the University of Colorado School of Medicine. Pages 152. Cloth. Price $2.50. Baltimore: The Williams and Wilkins Company, 1930.

This book, complete in itself, is in a way supplementary to the author's previous work, "Stammering and Cognate Defects of Speech" (G. E. Stechert and Company, New York and London, 1913). It is intended, primarily, for school use, but is also written for those stammerers who must train themselves.

The book is divided into two parts. The first, "Stammering—An Impediment of Thought," comprising the first four chapters, is given over to a brief consideration of the general characteristics of stammering and to the statement of the writer's theory that stammering is a phase of psychoneurosis in which the afflicted individual is confronted with a momentary break in the continuity of consciousness regarding more particularly the auditory component of verbal image, namely, "stammering is an impediment of thought and not an impediment of speech."

In part two, the remaining eight chapters, "Thought Training as the Basis of Speech Correction," the author discusses the principles of speech correction and their application to kindergarten children and grade-school children, and adults and high-school children. Bluemel feels that before any and every attempt at speech the pupil must "tranquilize his emotions, formulate his thought completely" and breathe correctly. The particular responsibilities of the instructor and of the parent are then given special consideration and the writer concludes the work proper with a word of advice to the student.

This book is clearly and concisely written throughout and is most logical and sincere. It is a work which well deserves the careful consideration of the older children and adults who stammer and the parents of children who present this problem, as well as that of physicians and educators who are intimately associated with such individuals.

Walter P. Gardner, M.D.

FOR SALE—Small rural hospital. All modern. Worth $25,000. Will sacrifice for $16,000. Instruments and equipment included. $5,000 cash. Balance time at 6 per cent. Address D-130, care Minnesota Medicine.

WANTED FOR IDEAL ST. PAUL LOCATION

Pediatrician, eye, ear, nose or throat or other practitioner in special line to share office with energetic general practitioner and long established very successful dentist. Over flourishing drug store at Grand and Snelling Avenues, across from Macalester College, one block from Summit Avenue. Owner will subdivide space about 17 x 20 in second story to suit tenant. This second story is just being built over drug store. Space offered leads off large reception room shared with general practitioner and dentist. No chiropractors or other irregulars in building. Call John Fitzgerald, Cedar 1952.

WANTED—Salaried appointments for Class A Physicians in all branches of the medical profession. Let us put you in touch with the best man for your opening. Our nation-wide connections enable us to give superior service. Aznoe's National Physicians' Exchange, 30 North Michigan Ave., Chicago. Established 1896. Member The Chicago Association of Commerce.

WANTED—Position as physician's office assistant and clinic technician by experienced stenographer with technician's training. Call Dale 3593, or address D-135, care Minnesota Medicine.

EXPERIENCED LABORATORY TECHNICIAN wishes position in doctor's office or hospital. No objection to some office work. Address D-136, care Minnesota Medicine.

FOR SALE—Number of surgical instruments at reasonable price. Address Mrs. W. S. Leech, Roseau, Minn.

Vol. XIV JULY, 1931 No. 7

RADIO AND QUACK MEDICAL PROPAGANDA*

H. A. Bellows
Vice President, Columbia Broadcasting System, Inc., and
President, Northwestern Broadcasting, Inc.
Minneapolis

IN addressing such a group as this I feel that any layman must necessarily apologize in advance for his inability to speak the language of his hearers. Regarding most phases of the subject about which I am going to talk to you, the advertising of patent medicines and quack remedies, you all know a great deal more than I do. The only phase of it on which I may be able to give you some information is the broadcasting one. In order to do this, I shall have to dig into another of the learned arts, with which I am only a little more familiar than I am with medicine: the law. Considering, then, that I am going to talk to you about certain applications of the law to medicine, and begin by saying that I know nothing of either subject, you can well see how thoroughly qualified I am to address you.

I want to begin by saying that I regard the use of radio broadcasting for propaganda in behalf of fake medicine as constituting one of the most serious perils which the public health of America has to face. There are now, in round numbers, fourteen million radio receiving sets in use in the United States, and it will not be long before this figure is up to twenty million. Now, the most important feature of practically every one of these receiving sets is that it is in use in the home. It is used by every member of the family. Babies unable to walk are taught to crawl to the radio set and turn it on; Great-Grandpa, after he has ceased to be useful for any other purpose, can still play with the dial.

Another important thing to note is the general decrease in the price of receiving sets. There was a time when radio reception showed a certain amount of selectivity for the reason that receiving sets cost enough so that a great many homes could not afford them. Now, however, commercial sets are available at prices which put them within the reach of almost everybody.

All this means that radio today has a total circulation infinitely greater than that of any other single medium of communication. A program on either one of the two great national chains can reach practically every one of these fourteen million receiving sets. Compare this figure with the circulation of, say, three million claimed by the largest of our periodicals, or with the several hundred thousand of a metropolitan newspaper, and you can readily see the tremendous potential importance of radio as a medium of publicity.

Nor is this all. I do not need to tell you how much more effective an appeal can be made to the ear through speech than to the eye through the printed page. To begin with, there are enormous numbers of people to whom reading is an effort. Their minds respond with difficulty, if at all, to what they see in print. These are the classes of people who are most likely to be influenced by unsubstantiated claims for medicines and alleged cures. They are credulous, gullible and the victims of unfulfilled hopes.

Another thing to consider is the curious authority which radio enjoys with the great mass of its listeners. This comes, I think, largely from the element of magic which enters into our feelings about anything we do not understand. The newspaper reader, although he cannot tell you accurately how the paper is printed, has flattened his nose against the windows of a printing establishment long enough to have a vivid picture of how the presses revolve. The newsboy who delivers the paper at his door is a familiar urchin, probably his next door neighbor's son.

---

*Presented before the annual conference of secretaries of the component societies of the Minnesota State Medical Association, Saint Paul, February 7, 1931.

There is no magic in any of this. But when he goes to a little wooden box and turns a switch, speech and music come to him out of nowhere. It is small wonder that he does not know what is happening, because the greatest engineers are only a little better informed on the subject than he is.

After all, there is a good deal of magic about radio, and the messages that come over the air have very definitely a peculiar significance. People tend to believe in them because of the manner in which they come.

This is clearly shown by the way in which such broadcast statements produce action. In general, we all complain that we write and speak and work without producing any particular results. People may listen to us, or watch us, or read what we write, but as a general thing they promptly proceed to forget all about it. Not so with radio.

I have gone into so much detail in order to make you realize what I am pretty sure you understand already: the tremendous potential power of radio broadcasting. I want to make it plain that this power is very much greater than would be indicated by the actual number of receiving sets, great as that number is. It is a power which combines vast circulation with the effectiveness of a medium appealing to all classes of people, and appealing with particular force to that class of people whose judgment has not been trained by education. In other words, it is a particularly fertile field for the quack medicine advertiser.

This brings me straight to the question of the commercial status of broadcasting. First of all, I want to make it plain that, taken as a whole, broadcasting has not as yet made any money. It is perfectly true that the volume of radio advertising has enormously increased, particularly in the past two years, but it is equally true that the cost of operation has fully kept pace with revenue. This has been largely because of the need of new capital expenditure. Radio communication is so new, and is developing so fast, that equipment becomes obsolete almost before it is installed. There is hardly a first class radio station in the country that is using today the same studios of which it was so proud five years ago. Transmitters have either been completely rebuilt or are on the way to the scrapheap to make way for newer and vastly more expensive ones. When, in 1925, WCCO began operating its 5,000 watt transmitter, it was the last word in broadcasting construction, and everybody called it a "super-power" station. Today we are completing plans for the construction of a 50,000 watt transmitter, ten times as powerful as the old one, and nearly ten times as expensive.

Another thing I want to try and make clear is that the ownership and operation of a broadcasting station is not in itself a particularly good advertisement for the owning and operating company. There is a very close analogy in this between broadcasting and the newspaper business. For example, it presumably pays the Northern Pacific Railroad to advertise in the *Saint Paul Dispatch,* but it presumably would not pay the railroad to own the *Saint Paul Dispatch.* Exactly the same thing is true in radio. When, for example, Washburn Crosby Company, now General Mills, Incorporated, built the present WCCO, the Company believed that the ownership and operation of the station would help to sell Gold Medal Flour. I very much doubt if it has done so to any marked extent. On the other hand, General Mills is thoroughly convinced of the value of radio advertising. It actually accomplishes more in the promotion of sales by a single half-hour program once a week over WCCO than it did through all the announcements of its ownership of the station in the days when WCCO was actually owned and operated by Washburn Crosby Company.

What this means is that there is no longer any hope that broadcasting stations can be operated, as they were in the beginning, simply as publicity agents for their owners. For a long time it looked as if the stations owned and operated by newspapers might be exceptions to the general rule. The newspaper stations were, as a class, the last ones to go into the business of selling time, but even with these stations the owners found that any definitely traceable good which their companies were deriving from the ownership and operation of the station was nowhere near as much as could be purchased spending the same amount of money another way. In other words, it is far more effective advertising to put a commercial radio program on forty different stations than it is to put forty of your own programs on one station.

With our whole structure of radio broadcasting based on the use of radio for advertising, and with broadcasting stations as a whole just about breaking even, particularly in view of the evident necessity of heavy capital expenditure within the next few years, it is perfectly obvious that there is a good deal of a scramble for business. And because, for the reasons I have already given, radio is a peculiarly effective medium for alleged medical advertising, the manufacturers of patent medicine, and the sponsors of so-called "cures," have been among the foremost to try and purchase time. The number of these prospective clients for broadcasting, and also their persistence, are growing steadily. Not a day passes without bringing to WCCO one or more orders from patent medicine manufacturers, all of which, of course, are promptly turned down. So far as immediate returns go, I suppose our policy in this matter has cost us easily a hundred thousand dollars in the past twelve months. I do not in the least regret the position we have taken, because I believe that the general standing of a broadcasting station in its community is in the long run infinitely more important than its immediate profit, but I want to make you see why so many stations have yielded to temptation.

Of course the real question is: What are we all going to do about it? In order to give you the background, I have to discuss for a few minutes the special laws under which broadcasting operates. As many of you know, I was one of the original members of the Federal Radio Commission, and through my work in Washington, and also as chairman for the past three years of the Legislative Committee of the National Association of Broadcasters, I have had occasion to study the radio laws pretty carefully.

First of all, broadcasting has been definitely held to be interstate commerce. The whole structure of our radio law is based on the power given to Congress by the interstate commerce clause of the Constitution, and the courts have upheld this view without qualification. In one instance a case was brought by a little station which attempted to deny the authority of the federal government on the ground that the station could not possibly be heard outside the limits of its own state, and that therefore its regulation was purely a state matter. The court, however, held that even in this case the possibilities of interference crossed the state line, and that all broadcasting was therefore to be considered as interstate commerce.

This means that there is practically no hope of any effective regulation of radio broadcasting through state legislation. One or two states have actually tried to pass radio laws of their own, but in every case, so far as I know, these laws have been found unconstitutional by the courts just as soon as they varied in any respect from the federal law. Any attempt to put a curb on the activity of any radio station through state legislation is practically certain to result in failure, for the simple reason that the state courts simply will not accept jurisdiction.

Now let us see what the Federal law provides. The Radio Act of 1927 makes it mandatory upon the licensing authority, which is the Federal Radio Commission, to issue a license to any station if it can be shown "that public interest, convenience or necessity will be served thereby." Now, nobody knows what "public interest, convenience or necessity" actually means. The phrase has never been fully defined by the courts, and probably never can be defined by anybody.

Any radio station can make a convincing showing that the public is interested in its operation. The redoubtable Mr. Henderson, whom some of you may have heard, brought to Washington several huge bales full of signed affidavits from listeners to the effect that his station was the best on the air. I remember a little 10 watt station down in Iowa, the existence of which seemed to me a doubtful blessing. I asked the owner of it if he thought he was really doing anybody any good by running his station. He undertook to show me, and he did so by producing, in about a week, over ten thousand letters from listeners telling him how much they enjoyed his programs.

Furthermore, the radio law as it now stands does not give the Federal Radio Commission authority to revoke a license as a method of punishment, though an amendment giving this authority has just been introduced. Violations of law by a radio station are subject to punishment by fine or imprisonment, and action has to be taken through the Federal District Attorney. This explains why certain radio stations which have conspicuously violated the law, or which have been operated in clear violation of public decency, are still enjoying licenses from the Commission; the poor old Commission simply has not the power to revoke their licenses unless it can affirmatively prove that their operation is not "in the public interest, convenience or necessity."

There is one more provision of the Radio Act which is important in this connection. It is specifically provided that "nothing in this Act shall be understood or construed to give the licensing authority the power of censorship over the radio communication or signal transmitted by any radio station, and no regulation or condition shall be promulgated or fixed by the licensing authority which shall interfere with the right of free speech by means of radio communication." If you will stop and think of this clause for a moment, you will see that it practically deprives the Federal Radio Commission of any power whatsoever in putting a stop to misleading or fraudulent statements made over the broadcasting stations which it licenses. Congress was so anxious to restrict the power of the Radio Commission to the purely technical side of its work that it took away all power of controlling the use to which its licenses might be put.

With the law in its present state, I think it is useless to look to the Federal Radio Commission for any direct action in checking or restricting the broadcasting of quack medical advertising. There is, indeed, one rather clumsy piece of machinery which can be set in motion. If the Federal Trade Commission certifies to the Radio Commission that a station is being used for fraudulent or untruthful advertising, the Radio Commission can officially take cognizance of the fact, but only to the extent of telling the station owner that the particular piece of radio advertising complained of must be modified or discontinued. Considering the fact that it takes a long time to get the Federal Trade Commission to act, and that even after it has acted the remedy is so lamentably inadequate, I cannot say that this method of trying to remedy existing conditions is very useful.

So far as the Federal laws applying particularly to radio are concerned, the only hope I can see is in the possibility of an amendment by Congress to the Radio Act. You know far better than I do the difficulties of preparing such an amendment. I believe, however, that it might be possible to draft a general clause, making it illegal to broadcast any fraudulent statement of fact, or any statement which the station owner or the advertiser knows to be untrue. Such a clause is at best very difficult to manage, because it involves specific proof of fraud, but such an amendment, if carefully drafted with the approval of the entire medical profession, would certainly help the Federal Radio Commission by giving it much needed authority and might be of real service in some cases of patent medicine advertising.

Frankly, however, I have not much faith in the power of legislation to curb this type of advertising. I do not believe that a law can be drafted which will not have a lot of holes in it, nor do I believe that the enforcement of such a law would be much more effective than the enforcement of certain other laws which I have heard mentioned. I believe, therefore, that the best way to guard against the danger is through the use of existing laws covering slander and false statements, and above all through direct application to the broadcasters themselves.

As regards existing laws, the main trouble in applying them to broadcasting is to establish a clear proof of what is actually being said. For example, I was at one time involved in a very important case between two stations, one of which was sending out a tremendous amount of fake medical advertising. We had public stenographers make transcripts of these advertising announcements, but we found that these transcripts, although presented in the form of affidavits, were not acceptable to the court. It was not until we took dictaphone records of the programs of the station in question, including the objectionable advertising, and then produced the dictaphone record man himself in court to testify regarding the whole proceedings, that we were able to get the information in such form as to be effective.

There have been, however, a few cases in which stenographic transcripts of what has been said over the air have been adequate as evidence. One station in Iowa may soon, I hope, be compelled to discontinue a series of talks advertising an alleged cure for cancer as the result of stenographic records brought into court. This method may prove effective in the most acute cases, but it is available only when the statements are of a very extreme kind, and I do not believe it can accomplish much in preventing the ordinary run of patent medicine advertising.

By far the most effective way to stop this kind of advertising is directly through the pocketbook of the station owner. Radio advertisers are, as a rule, inclined to be very particular as to the company they keep. Before an advertiser signs a contract he is sure to ask what program will come just ahead of his own, and what one will follow. This is natural, because radio advertising is so largely dependent on creating good will among the listeners. The circulation of a broadcasting station depends solely on the number of people who want to listen to it, and once a station becomes thoroughly offensive to a particular class of listeners, it can count them definitely out of its audience.

Now, if a station advertises patent medicine, it is not a particularly good advertising medium for clients of a more respectable sort. And there is one thing about the patent medicine advertisers that makes them, as a class, undesirable clients for even the least scrupulous broadcasting station. Practically all of them want to broadcast simply short announcements. Almost never do they want to put on real programs. They like to tell their story in a hundred-word announcement every day, or at most, a five minute talk.

Now, what the radio station wants is the advertiser who will buy at least half an hour of time and pay for a real program. If such an advertiser says to the station owner that, although he would like to use his station, he really cannot bring himself to do so because of the number of objectionable patent medicine advertisements, the broadcaster is going to do some heavy thinking. He cannot afford to lose the good advertiser who wants to put on real programs, and he is going to do everything he can to take care of him.

More and more, I believe, reputable advertisers are going to refuse to buy time on stations which accept objectionable medical advertising. Of course there are always going to be certain stations which will depend on undesirable advertising for their main revenue, just as there are publications that do exactly the same thing, but if we can keep objectionable medical advertising off of all the larger stations, the amount of harm which can be done will be very materially cut down.

More important still is the direct appeal to the broadcasters themselves. The National Association of Broadcasters has adopted a fairly definite policy in this respect, but like all trade associations, its power over its individual members is relatively weak. I believe that the best thing the American Medical Association could do would be to approach the National Association of Broadcasters with a definite proposal for a regulation to be adopted by the association of broadcasters and sent to all members. Then it would be up to the various state medical associations to keep in touch with the individual stations and see that they live up to this regulation. Speaking as one of the directors of the National Association of Broadcasters, I can pledge the whole-hearted support of that organization to any such movement, and I believe the first step should be taken by the medical association.

With WCCO, we have a very satisfactory working arrangement with the Minnesota State Medical Association, which has given us constant and splendid coöperation. Under the terms of our agreement with the Association, we refuse to broadcast any medical advertisement or talk unless it is specifically approved in advance by the State Medical Association. This, of course, means that no such material ever gets on the air from WCCO.

After all, broadcasting, which can be carried on only by virtue of a Federal license, in other words, a license from the people, is to some degree a matter of public service. This is recognized in the vague language of the Radio Act, "public interest, convenience or necessity." It is manifestly not in the public interest that the privilege granted by a Federal license should be used in such a way as to endanger the public health. If it is persistently so used, Congress will have to find a way to stop it. I believe, however, that before this happens, the broadcasters will see the wisdom of putting a stop to it themselves. Some of them understand the situation already, but a great many others will understand it only if the facts are brought to their attention in direct relation to the inevitable consequences to their pocketbooks. Just as soon as a broadcaster can be made to see that his desirable advertisers will leave him, or desirable prospects will not sign contracts, if he persists in broadcasting objectionable medical advertising, he is either going to discontinue the offensive advertising or is going to relegate himself to the class which has very few listeners. I believe the time has come for concerted action in this direction through the combined efforts of the American Medical Association and the National Association of Broadcasters, with the clear understanding that whatever is done must be followed up thoroughly and energetically by the state medical associations. I am convinced that such action will produce very desirable results, but if it should fail, there is nothing for it but to go to Congress and insist on the passage of additional legislation to prevent the use of a public license to the injury of the public health.

SKETCH OF THE EARLY HISTORY OF THE AMERICAN MEDICAL ASSOCIATION*

E. Starr Judd, M.D.
Rochester, Minnesota

THE origin of the American Medical Association can be traced to a national convention of delegates from medical societies and colleges called by the Medical Society of the State of New York. This meeting was called for the purpose of raising the standards of medical education. This first national medical convention met at the New York University May 5, 1846. After much opposition and indignation this session continued the making and discussing of resolutions all of which were to be referred to committees to be reported back to a meeting in Philadelphia the following year.

The national convention composed of nearly 250 delegates met in Philadelphia May 5, 1847, and resolved itself into the first session of the American Medical Association. According to the historians, in this meeting of three days' duration, work was outlined which was to occupy the society for the next fifty years. All through the historical articles repeated mention is made of raising the standards of medical education. A code of ethics was established. A constitution was adopted which encouraged the formation of state and county societies. The person who deserves more credit than any other for the beginning of this great medical organization is Nathan Smith Davis. For more than sixty years Dr. Davis worked for the highest ideal in medical education, organization, and journalism. He joined the faculty of Rush Medical College in Chicago, in 1849, and, in order to work out his own educational ideas, later founded the Chicago Medical College, of which he was dean for more than forty years. His name also appears among the founders of the Illinois State Medical Society, Chicago Medical Society, Mercy Hospital, Academy of Sciences, and Northwestern University. Dr. Davis was the first editor of the *Journal of the American Medical Association.*

In these early days, there was much discussion about higher standards of medical education. At that time the annual courses of many of the medical schools occupied only four months, and the curriculum was very inadequate. In these early years a great deal was said about preliminary education. Discussion brought out the fact that medical colleges were resentful of any attempt at regulation and each one feared to raise its own standards lest some other college in some other state would offer a more attractive bargain to the prospective student.

In 1848 authorities of colleges opposed the very modest requirements in preliminary education which had been suggested, and also opposed the extension of the term of lectures to occupy six months, because, as they said, such standards would impose unnecessary burdens on the student and deter many from studying medicine. The practitioners however favored anything that made it more difficult for medical graduates to multiply.

For many years after the American Medical Association was organized, there was much discussion as to who was entitled to membership in it. The original intention was to limit representation to state societies in regions where such organizations existed; local societies would be represented only if there was no state organization in the same region. Medical colleges, hospitals, asylums, and so forth, had representatives in the original organization.

Nathaniel Chapman was elected first president of the American Medical Association; although he had not been active in its organization, he was nevertheless one of the oldest and most eminent teachers of his time, and stood at the head of the profession. Evidently he was not very enthusiastic about the medical profession at that time, for in his presidential address he observed that the profession to which he belonged, "once venerated, has become corrupt and degenerated to the forfeiture of its social position and, with it, of the homage it formerly received."

At the meeting in 1848, Oliver Wendell Holmes urged American physicians to produce their own literature instead of republishing European works.

In 1850, for the first time, the American Medical Association held its meeting in a western city, in Cincinnati, and it is said that this meeting gave new and strong impulse to the work of organization throughout the profession in the western states. All previous regulations on medical education were reaffirmed.

---

*Presented before the annual conference of secretaries of the component societies of the Minnesota State Medical Association, Saint Paul, February 7, 1931.

The social organization was still more active at the meeting in 1851, in Charleston, S. C. Entertainment of the delegates was featured by a trip by steamboat up the river, to visit a rice plantation, and by an elegant and costly public dinner at which the historian, who was always an ardent teetotaler, "regrets to report that for the first time in the history of the association wines and strong drinks, which beguile the unwary and intoxicate the brain, were freely furnished." Three years later, after a still more elaborate entertainment had been provided by the members of the profession in New York, a resolution was adopted recommending to all future committees that they dispense with all costly and extravagant entertainments. At the meeting in Charleston, for the first time, steps were taken to form a separate section for the reception and discussion of original scientific papers, which up to this time had been given very little attention on account of the urgency of matters concerning policy and organization.

In 1852 it was recommended that no medical college should send delegates to the Association: (1) unless it have six members on its faculty, (2) unless it give one course of instruction annually of not less than sixteen weeks in the fundamental sciences, and surgery and midwifery, and (3) unless it requires its candidates for graduation to be twenty-one years of age, to have studied three years with some respectable practitioner, to have attended two full courses of lectures, not in the same year, and to have shown by examination that they were qualified to practice. In these years, the Association had no means of enforcement of its rules and in many ways progress seemed very slow.

In the early part of the Civil War there were no meetings, but in 1863 the Committee on Medical Education reported that reproach and distrust of the medical profession was felt everywhere, and that the chief cause of weakness of the medical profession was lack of preliminary education.

Attendance at meetings continued to grow larger and the work became more complicated, so that questions that arose often could not be decided in open meeting. Therefore in 1873 a judicial council of twenty-one members was created to take charge of and decide all questions of ethical or judicial character that might arise.

At the meeting in 1874 a plan of organization was discussed but it seemed impossible to get properly accredited delegates to take the time to do the work and make the decisions, and it was not until eight years later, at the meeting in Saint Paul, that effective steps were taken toward this end.

Up to 1882 the scientific papers had been published in the annual transactions and were essentially buried there. The annual membership dues at this time were $3.00 and the income to the Association varied from $2,000 to $6,000. The American Medical Association at this time was described as an organization without funds, without a definite permanent membership, which held an annual mass meeting of delegates from various societies, often with no mutual bonds.

At the meeting in Saint Paul in 1882 it was estimated that the publication of a journal would require $15,000 annually. It was decided to open the membership to all members of state and county societies, to increase the dues to $5 annually, to secure a charter, to appoint a board of nine trustees, and to establish a weekly journal. In July, 1883, the first number of the *Journal of the American Medical Association* appeared. In 1897 the Association was incorporated in the State of Illinois.

The publication of the journal was of the greatest importance, but the organization was becoming so large and unwieldly that many difficulties arose at each meeting. There seemed to be no way of marshalling so huge a membership for the organization and conduct of affairs. Many attempts were made to reorganize, and a committee which was appointed in 1886 had attempted for years to get action on its report, which was finally laid on the table. In 1900 a committee consisting of Doctors McCormack, Foshay and Simmons again began working on a plan for revision of the constitution and by-laws. The outstanding feature of the new plan was the proposal that a Business Section should be constituted to be known as the House of Delegates, the membership of which was not to exceed 150, the members to be elected by the state societies only. From this time the association has remained an absolutely democratic organization.

William H. Welch, at the close of his presidential address before the Association in 1910, said: "Among the organized forces for advancing the prosperity, the happiness, and the well being of the people of this country, the American Medical Association has an important part to play. We are justified in the confidence that, with the united support and loyalty of the profession, this association, broadly representative and standing for the best ideals of medical science and art and for professional and civic righteousness, will contribute a beneficent share to the working out of our national destiny."

Meetings held in 1882 and in 1901 were important from the standpoint of completing the organization of the national society.

The convocation held in 1901 at the Ryan Hotel in Saint Paul marked the reorganization of the American Medical Association. John F. Fulton was chairman of the local committee on arrangements.

A. W. Abbott of Minneapolis was the first delegate from the Minnesota State Medical Association to the House of Delegates of the American Medical Association.

Both the meeting held in 1882 and the one in 1901 were held in Saint Paul.

THE CENSORSHIP OF MEDICAL AND DENTAL ADVERTISING

One of the primary reasons for the establishment of the Council on Pharmacy and Chemistry of the American Medical Association in 1905 was the desire of the editor of The Journal of the American Medical Association for scientific advice concerning claims made by advertisers for proprietary remedies. The Board of Trustees of the American Medical Association give the fullest support to the Council by refusing space in the advertising pages of publications of the American Medical Association to advertisers of proprietary remedies who failed to meet the Council's requirements. With that support the Council has made its work and its name respected. The advertising pages of the publications of the American Medical Association and of the state medical journals that coöperate afford a striking contrast to the pages of the *British Medical Journal* and of the *Lancet* (London), which exercise a so-called censorship without, however, having behind the censorship the type of scientific study and control represented by the Council on Pharmacy and Chemistry. The Council on Dental Therapeutics of the American Dental Association began its work with high ideals and with enthusiasm. In 1930 the trustees of the American Dental Association adopted a resolution to place the association squarely behind the Dental Council in its efforts. Then, at the midwinter session of this association, held in February, 1931, the board of trustees practically reversed its previous action, placing the business manager of the periodical in a position of judgment over the council and making him arbiter as to whether or not the criticisms of the council shall be referred to the manufacturer. Without the power of the trustees of the American Dental Association and the periodical of the association wholeheartedly behind its work, the Council on Dental Therapeutics will be ineffective. (Jour. A. M. A., May 16, 1931, p. 1697.)

EXPERIENCES IN COUNTY MEDICAL ORGANIZATION*

THEODORE WIPRUD
Executive Secretary, The Medical Society of Milwaukee County
Milwaukee, Wisconsin

WHEN your genial Secretary, Dr. Meyerding, visited Milwaukee a few weeks ago and spoke to me about coming to St. Paul, he gave me explicit instructions as to what I should talk about. Among other things he wished me to emphasize our experiences in county medical organization and asked that I theorize as little as possible. I am afraid that Dr. Meyerding takes the same view of a discussion of medical organization that the scientist did of the law of gravity, when he said that a man who fell over a cliff did not break the law of gravity, he illustrated it. Dr. Meyerding evidently feels that illustration is more effective than theory. True as this may be, I will have to deviate a little from his expressed wishes. It is important, it seems to me, that we have a little background for a discussion of what we have been attempting to do in Milwaukee.

The growing importance of the county medical society has become increasingly evident. I was particularly impressed with this at the last session of the American Medical Association at Detroit because it seemed that every official who spoke, from the President down, emphasized that the county medical society was the most important cog in organized medicine.

Problems confronting medicine have become so complex and varied that it is small wonder that leaders in medicine are stunned by their magnitude. For any single organization or institution to give thorough consideration to modern medical problems in all their phases would be a practical impossibility. The American Medical Association does not presume to do such a thing, and perhaps wisely suggests that many problems are so interwoven with the social and economic fabric of our country that they cannot be isolated. There is, undoubtedly, a large measure of truth in this, but it is also true that the smallest unit of the American Medical Association—the county medical society—has it within its power to meet many local problems which in a large measure make up the major difficulties. Conditions vary greatly in various sections of the country. What would be a solution for public health problems in Milwaukee might raise havoc in Cleveland. A program that would be approved in St. Paul wouldn't necessarily be acceptable to Minneapolis. It is evident then that the county medical society, which we may say is on the fighting line of medical practice, will undoubtedly have a great deal to do with the solution of many medical problems, and that no light responsibility rests on this unit of organized medicine.

To meet the demands which are made upon it the county medical society must be organized. This does not mean the loosely organized unit which has become so familiar, where infrequent scientific meetings comprise the sole activity. It means a unit that will not only improve its members scientifically, but will also assume its responsibility in other directions, not least of all to the community. To do this effectively a full-time secretary or a member who can give a large portion of his time to Society activities is needed. In large centers a part-time secretary has a thankless and difficult job. He cannot possibly do justice to the job entrusted to him and still give adequate attention to his practice.

In the last few years a number of societies have employed laymen as full-time secretaries. At the present time there are twelve or thirteen large cities where laymen are entrusted with the executive work. So far as I have been able to determine, these laymen have been successful, and the societies employing them are satisfied with the work carried on. Outstanding work has been done in Cleveland, Detroit, New York, Toledo, and other cities.

I have sensed some opposition to laymen as officers of medical societies; undoubtedly, there are legitimate reasons for this attitude. The objection may be raised that the layman's background is not such that he can get the medical man's point of view. And then, of course, he does not have medical training, and therefore cannot understand the more important phases of the practice of medicine. In view of these shortcomings, it is contended he cannot make the proper approach to the most important functions of a county medical society.

---

*Talk given before the annual conference of secretaries of the component societies of the Minnesota State Medical Association, St. Paul, February 7, 1931.

On the other hand, there are many who feel that a layman can soon acquire a proper background for medical organization if he is intelligent and adapted to the work. The lay secretary, they feel, has many advantages over a physician in a similar position. He can approach problems which the physician would find extremely difficult if not impossible to handle. No one can contend that he is seeking prestige or that he has "an axe to grind." He views the problems of the organization from a fresh point of view, and, if he is wise, will discharge his duties after careful thought and counsel with able medical men of his society. In approaching community problems he is particularly well fitted, and can speak for the physician as the physician could not speak for himself. As the business manager of the society he should be much superior to the physician.

It would be presumptuous of me to draw any conclusions from these points of view. Whatever the reaction is the layman will undoubtedly play an important part in medical activity in the future. If he is conscientious and able, the thinking medical man will give him the credit that is due him.

Some years ago Herbert Quick wrote a book. He called it "One Man's Life." I thought it a mighty good title for autobiography. In relating a little of my personal experience that title occurs to me as applicable. You will, of course, overlook my personal references, knowing that Dr. Meyerding is responsible for my making them. He wishes you to have a look at the background for the work which one executive officer of a county medical society is doing.

Most of the laymen who have become identified with medical organizations were either newspapermen or lawyers. I was neither. For a number of years I was in the banking business. That sounds a lot better than it is, as any young banker will tell you. While serving as cashier of a bank in Northern Wisconsin I was urged by two physicians to join their hospital as business manager. Although skeptical I joined them, and became intensely interested in their work, serving in every capacity that I could. In the course of some eight years with these men, I learned much about physicians and their problems, which is now standing me in good stead. We enjoyed the satisfaction of building up an institution in that small community, which was unique and which served a large territory well.

Some years after joining these physicians I had occasion to speak at a medical meeting in which several adjoining county societies participated. It happened that the Secretary of the State Medical Society was there. He was impressed with my talk on collecting physicians' accounts and later published it in the state medical journal. As an indirect result of this incident I eventually joined the Medical Society of Milwaukee County.

A rather unusual situation existed in Milwaukee prior to the inauguration of their new program with a full-time secretary. Difficulties between the Health Department and the medical profession had multiplied with consequent ill feeling. Newspapers were none too friendly, and seldom favored the medical profession's view of any subject under discussion. This in itself was not unusual, but the fact that other organizations were the source of medical information and that a privately owned physicians' telephone exchange served over 200 physicians, was unusual. Officers of the Society had been disturbed by the possibilities of this telephone exchange under private management. While it was then being ethically operated, under different management it might be a source of great danger to the prestige of the medical profession of Milwaukee.

After careful deliberation, a survey of conditions existing in other cities was decided upon. The Academy of Medicine of Toledo had long sponsored a telephone exchange similar to the privately-owned one in Milwaukee, and employed a full-time secretary, and this was the first point of contact made by the officials of the Milwaukee Society. Following their survey of Toledo activities, the purchase of the privately-owned exchange, or what we call the Physicians' Service Bureau, was decided upon. The next step was to employ for the Bureau a manager who would act as secretary for the Society. This was done on October 1, 1929.

I was informed when I accepted the position with the Medical Society of Milwaukee County that all that would be expected of me the first year was to make the Bureau successful. It was soon discovered, however, that while the success of the Bureau was important, it was only a part of an ambitious program into which we just naturally expanded. Problems kept arising on all sides, which clamored for attention and the Society was pressed to act. The result has been that more committee activities were carried on by our Society during the past year than ever before in its history. There were 85 meetings of the Directors and various committees in which 47 members participated. There could have been no more enthusiastic group. This is indicated by the minutes which reveal an average attendance of 90 per cent. This fine record was undoubtedly partly due to the wise action of the President in appointing small committees. Certainly small committees can accomplish more for a county medical society than large ones, since large committees are attended by about only half of their members.

One would suppose that considerable difficulty would have been experienced in getting men to serve actively on committees, as it seems traditional that committees in many county medical organizations are purely honorary, and that no work is expected of them. In recognition of the work done by our committees it must be said that they have not followed tradition or precedent. It is, of course, true that the Executive Secretary has often had to generate enthusiasm, and help committees keep clear of difficulties. In our scheme of organization the Executive Secretary is ex-officio member of all committees and acts as secretary—recording the minutes of all meetings. Sometimes the Executive Secretary's enthusiasm wanes; he becomes a bit wearied with the conflict of personalities and opinions, and is assailed with doubts and fears, but then these low moments are compensated for by the exhilaration which follows accomplishment.

What is of most importance in organization work as in other fields, is the result. A thousand committee meetings in a year would have no significance if nothing was accomplished. We feel in Milwaukee that for a first year program the results have been more than might have been expected. I am going to tell you briefly something about them and let you judge for yourselves. We might classify our accomplishments in two groups, those which may be called service to members and those which are service to the public.

I mentioned a moment ago the purchase of the Physicians' Service Bureau. This venture represented an investment of several thousand dollars, and on its financial success depended the first-year's program of the Society. The Bureau has proved exceptionally valuable to our members. To use the service a member must subscribe to the Bureau and pay a monthly fee, for which he is rendered twenty-four hour telephone service. The Bureau acts as a connecting link between the patient and the physician. We opened on November 1, 1929, with 220 members. At present we have 270. The equipment and personnel of the Bureau has been improved from time to time until at present we believe we have a very efficient service.

The Physicians' Service Bureau acts as an information bureau for the public. Calls are constantly received on every conceivable subject. Over 52,000 incoming and outgoing calls were handled last year. A third of these were inquiries. Most of them were for specialists. The procedure followed is to refer these inquirers back to their family physician. If they have no family physician, a classified list of specialists, approved by our Educational Committee, is referred to. Three names are given from which the inquirer makes his choice. When the next call is received in the same specialty the next three names are given. In other words the list is rotated. No information in regard to treatment is ever given by an operator.

Of course our scientific programs are an important feature. Attendance has so greatly increased that our officers have been much elated. An average attendance previous to last year was 100. This was increased to an average of 188. At four out of eight of our monthly meetings the attendance ran over 250.

This increase was partly due to the fine programs, the publicity given the meetings in our monthly publication, and the last-minute notices sent members. An added attraction was the social hour which followed each scientific meeting. This hour was given over to visiting and getting better acquainted. Buffet lunch was served during the social hour and physicians, being human, enjoyed this a great deal. We feel that this feature has helped to stimulate better feeling and understanding among our members.

One of the most interesting meetings held by the Society last year was devoted to medicine in its relation to journalism. The managing editor of one of our larger dailies spoke on "A

Journalist Looks at Medicine," and an able member of our Society returned the compliment by giving the physician's view of journalism. It was an exciting and profitable evening. Both speakers expressed themselves frankly. We hope to have another meeting of this kind.

A number of unusual activities were sponsored by the Educational Committee. Among them were courses in public speaking and medical writing. The public speaking course, which was given by Professor Ewbank of the Public Speaking Department of the University of Wisconsin under the joint auspices of the University and the Medical Society, was a decided success. Over 70 members enrolled. The course in medical writing, which is still in progress under Dr. Morris Fishbein, has attracted wide and favorable comment. There are 45 members enrolled in this course which is also sponsored by the Society and the University.

A survey has been in progress during the past year under supervision of the Social Medicine and Medical Economics Committee. The first survey completed was that of charity work being done by members of the Society in Milwaukee County. The results of this survey were published in our monthly publication, and later in the Journal of the American Medical Association, where they attracted wide attention. We have received letters from all parts of the country in regard to this survey requesting more facts about our report. This report revealed that our physicians were doing charity work valued at a million and a half annually, over most of which they had no control. Our survey is continuing in all fields of medical practice, and just now we are particularly interested in our county institutions. We feel that much will be accomplished by this committee.

A collection service operated under the supervision of the Society but not by it, has been planned, and we expect that it will be opened on or about March first. Some societies have had unfortunate experiences with such a service. However, others have done well, particularly when carried on as an enterprise separate from the Society.

Among the social activities was the first summer outing which was held at one of the lake resorts near Milwaukee. Over two hundred members and their families attended this outing, which will undoubtedly become a yearly event.

Much service is rendered members by the Executive Secretary and his staff. Requests for information of all kinds are received daily. An employment service is conducted for the convenience of members. Those desiring positions with physicians are interviewed, and their applications filed. A number of secretaries have been placed in physicians' offices. The Executive Secretary of course calls on members, and on several occasions has appeared before hospital staffs to speak on Society activities.

Our monthly publication, *The Milwaukee Medical Times,* we believe has stimulated the interest of our membership. It has been developed from a four-page folder to a forty-page journal. Many favorable comments in regard to its contents and appearance have been encouraging to the editors. The *Times* has been self-sustaining.

County medical societies all over the country are taking a more active interest in public health activities. It is important that they should. In fact the leadership in this field should logically be assumed by organized medicine, otherwise changes will come to pass in the field of private practice over which the medical profession will have no control. Particularly is this true in the larger cities.

Among other activities in this field sponsored by the Milwaukee Society is the Speakers' Bureau which provides speakers for lay organizations. Since its organization a little over six months ago, increasing demands have been made upon it. Daily we receive calls for speakers. People are interested in medical and health subjects, and many favorable comments are made upon our speakers by the organizations before which they appear. Lists of subjects are sent out to clubs, parent-teacher organizations, and other groups. They select the subject about which they wish to hear, and learn the name of the physician who will speak on it afterward. This Bureau will become increasingly useful.

All press information is given out through the Executive Secretary's office. Every effort has been made to give the newspapers legitimate and reliable information, and they have responded splendidly.

One of the sore spots in our medical situation was the strained relationship between the Health Department and profession. When I first assumed my duties I had a talk with the Health Commissioner. While he was frankly skeptical as to the result, he suggested an advisory committee of five members of the Society to meet with him monthly to consider problems of his department, which affect the medical profession. Results of this closer contact have been very satisfactory to all concerned. A better understanding and closer co-operation has been brought about. At this time no action is taken by the Health Department on any matter affecting the medical profession without submitting it for the approval of the Society. If I had time I should like to tell you of some of the results of this closer coöperation.

I will take the time to tell you of one co-operative activity. A joint campaign to eradicate diphtheria was sponsored by the Department and the Society last year. This at first was not successful because the Health Department immunized without charge, and the physician could not ask his patients to come to him, when free immunization was available. Later, however, the Health Department made toxin-antitoxin available free of charge to all physicians, and much was then accomplished.

Our Health Council, composed entirely of our members, was created last year. The Council was created for the purpose of developing a public health program in which the Society would assume leadership. More recently it was enlarged to include representatives of hospitals, and nurses' organizations, who will meet with the Council quarterly to discuss mutual problems. The first session of the enlarged group was held the first week of this month.

To touch on the subject of periodic physical examinations is to consider a subject which has been discussed to death. Despite this discussion leaders in medicine have seen little evidence that the medical profession by and large have been impressed with the importance of these examinations. It is evident to those giving the subject little thought that various official and non-official health bodies are pressing forward in preventive medicine, and that the trend of the times is toward prevention of disease. Unless the profession at large accepts this point of view and actually practices disease prevention, it would seem logical that the field will be left eventually to the various organizations who are urging preventive measures.

With this in mind, the Health Council is going to put forth a systematic effort to interest the rank and file of the profession in periodic physical examinations. First of all it will attempt to determine what comprises an adequate, minimum physical examination to be given by a general practitioner without laboratory and X-ray equipment available. Such an examination should be complete enough to reveal the necessity, if any, of extensive laboratory tests.

To prepare our physicians better for this work, practical postgraduate courses in diagnosis will be given. The first, which is to be given in March, will be an intensive course on the diagnosis of the chest diseases.

A number of other activities are considered by the Health Council for the coming year, and many problems have been presented to them for solution by various organizations in the public health field.

On a number of occasions the Society has taken active interest in public enterprises. During the past few months it has given free medical service to the Goodfellow House, a home sponsored by the Milwaukee Journal for homeless and unemployed men. No member has served more than once—an hour on a certain day, and although we have operated this service several weeks, there are still members available for this work.

Naturally I have just hit the high spots in our program. While there is much tangible evidence of progress, we feel that the intangible accomplishments have been of equal if not more importance. The prestige that the Society has gained in the past year because of its improved organization has placed us in a different and superior relation to all outside groups. Daily we are impressed with the value of this increased prestige. One evidence of it is shown by the constant seeking of advice and approval of the Society by organizations and individuals who never heretofore gave the Society consideration.

While an extensive program such as ours cannot be carried on by county societies in rural communities, it is surprising what they can do. Last summer I visited my old home, the village of Frederic, Wisconsin, which, as many of you know, is located about eighty miles north of St. Paul, in the northern part of Polk County. For a number of years the medical men in the county have belonged to a five-county medical society. Last summer they were considering an independent county society in Polk County. I took occasion on my visit to urge their separate organization and in a talk given to the society pointed out what they might accomplish in the public health field and in that of social medicine and medical economics.

Since my visit Polk County has its own society, and has as its secretary a layman who is a business manager for a group of physicians at Frederic. The local paper, which I receive, indicates that they have a live society indeed. Regular monthly meetings have been excellently attended, and much interest and activity have been manifest in public health problems. Many economic problems, I observe, have been threshed out to the mutual advantage of every physician. What is most pleasant to record, there is more harmony among the medical profession than there has ever been in that part of the country. So it is apparent that whether the county society is large or small, organization can be just as effectively promoted to meet demands made upon it.

Medical men are liable to become soured on conditions which exist in the medical field today, and vent their feelings on the public. They are hardly to be blamed for remonstrating, particularly with those who know little about medicine yet contribute scathing essays on medical practice to the leading periodicals of the county. Medical men might well assume the attitude of the Confederate soldier who was trudging through the mud. Suction of the wet and sticky mud made going slow and difficult. An officer observing that the soldier was lagging rode up and bawled: "What is the matter, you? Move along." The soldier looked up in anger and despair and said: "If I ever love another country, damn me."

The bitter and antagonistic attitude of some medical men, however, does not seem justified. Problems which confront medicine may best be approached in a friendly and sympathetic attitude. Of course, this does not mean a spineless attitude.

As in all great organization activities, vision is needed in the medical field today. Better organization, a unity of purpose, and a vision which sees beyond the present and includes the possibilities of the future are essential. If the county society meets these requisites it will serve its membership and its community in full measure.

A POINT OF VIEW IN MEDICINE

E. C. Hartley, M.D.
Saint Paul

HOWEVER much the physician of today may desire to sit still, the forces directed upon him from within his profession and from outside it are too active for repose. To remain passive in the midst of this active play of opinion seems to him to press passivity to the point of stupidity. He cannot meditate on an alternative, as did Pascal and find a virtue there: "I have often said that all the troubles of man come from his not knowing how to sit still. . . . So passes the whole of life. We combat obstacles in order to get repose, and, when got, the repose is insupportable; for we think either of the troubles we have, or of those that threaten us; and even if we felt safe, on every side ennui would of its own accord spring up from the depths of the heart, where it is rooted by nature, and would fill the mind with its venom."

The physician must be a stranger to ennui even though nature had made him a native to that pleasant state. Into his profession have been thrown an innumerable series of new ideas, new things, new tendencies—a witches' cauldron boiling up unceasingly new and wider demands upon him, new responsibilities. . . . He looks on in astonishment and in fear, for he rushes to an unknown destination *under acceleration.*

He is left restless and uncertain. Yet the nature of his duties and responsibilities demands a state of mind as far removed from those qualities as is possible. He may be restless with eagerness to learn, and the uncertainty of an active curiosity may well be his, but the gratuitous unrest that goes with an ambiguous position in society is not desirable. It is a distraction. The demands which society puts upon medicine today are in direct proportion to the promises made by medicine. These promises have a proven social value so great that they must be delivered, and it is in the very process of delivering these promises that distraction has entered. That a certain dissatisfaction results is to be expected.

In this equivocal position a respect for himself, for his profession, and for the public—his patients—urges the physician to define his position, his purposes, his relations.

He may well begin by a quantitative estimation of his profession in society. The results of even a casual review will astonish him by their dimensions, and reinforce his desire for an orientation which, even though it may well fail to define accurately his position, yet may at least indicate the direction in which he is moving.

He will learn that there are approximately 1,020,000 people who are ministering in one way or another to the care of the sick and the promotion of health. Of this number more than half are hospital attendants and nurses. Physicians and surgeons number 147,000; dentists 64,500; and retail drug dealers 80,000.

At the end of 1929 there were 6,665 hospitals averaging about 150 beds each; of these hospitals, 1,795 were controlled by some governmental unit, from county to national, and 4,870 were under private agencies, chiefly church, individual, or association. The bed capacity and the average number of patients in the government hospitals are almost double those in the private hospitals. The average number of patients in hospitals in 1923 was 553,133, and in 1929 this had grown to 726,766. Of this total, 395,407 were occupying a bed because of some mental or nervous disturbance.

Computations of the cost of disease runs into vast sums—for services of hospitals, nurses, dentists, physicians, and non-medical practitioners the figure is $2,000,000,000. For medicines it is estimated that we spend $700,000,000 annually. Of this total, according to value at factory, 50.3 per cent goes for patent and proprietary medicine for sale to the general public, 28.8 per cent for tablets, pills, powders, and miscellaneous products, including medicines for self-treatment and those sold through prescription. Ethical specialties dispensed upon prescription took 15.3 per cent, while the remainder, 5.5 per cent, went for biological products. While this sum, amounting to $6.33 per capita, was being spent for drugs, only $0.59 per capita was expended for public health work through local, state, and federal agencies.

In an Indiana county, a recent survey of the medical facilities, to be later incorporated in the report of the American Medical Association's Committee on the Cost of Medical Care, shows that the per capita expenditure was $21. Of this sum less than one-third was spent for medical advice and aid, while more than one-third was spent on drugs and medicines, of which, however, only 10 per cent was dispensed by physicians. The county has 31 physicians, 5 "active" chiropractors, and 6 Christian Science practitioners. Less than half the children in the county have been vaccinated, and less than 5 per cent of the school children under 10 years of age have been immunized against diphtheria. The county spends 1.3 per cent of its income on public health, that being least of all items on its budget.

Most agencies in the field of health may be classed broadly as official and as private or non-official agencies. The official agencies may be grouped under the various administrative units in our government. In the federal government itself there are twenty to thirty agencies doing some kind of public health work. The most important of these is the U. S. Public Health Service. The work of this Service is carried on under seven divisions, each of which is quite extensive and more or less of a unit in itself. The Children's Bureau of the Department of Labor carries on investigations in infant and maternal mortality and in children's diseases. This Bureau also administered the Maternity and Infancy Act. In the Census Bureau the Division of Vital Statistics carries on a work directly related to health. In the Department of Agriculture, the Bureau of Chemistry administers the Pure Food and Drug Act. The Bureau of Entomology studies the effects of insects on the health of man. In this same Department other bureaus, such as the Bureau of Biological Surveys, carry on activities which have some relation to public health functions. It is in this Department also in which the institution of County Agents and Home Demonstration Agencies, numbering about 5,000 persons, centers. They give an appreciable amount of attention to rural health work. In the Department of the Interior the Bureau of Mines is concerned with the health and safety of miners. The Bureau of Indian Affairs maintains a corps of almost 200 physicians and 86 hospitals for the care of Indians. The Bureau of Education gives special attention to school hygiene and physical education and also cares for the health of the natives of Alaska. In the State Department, the Consular Service gives weekly reports of sanitary and health conditions of various ports and issues bills of health to vessels leaving for the United States. In the Department of Justice, the Superintendent of Prisons is charged with the care and health of the federal prisoners.

The principle of federal subsidy may be mentioned here since the subsidy granted to the states under the Maternity and Infancy Act aroused such a protest from physicians on the basis of pernicious effects of federal subsidies. It is interesting to note that for the fiscal year of 1924 approximately $145,000,000 was issued to the states as federal subsidy, and of this amount less than $1,000,000 was used for all kinds of public health work.

Under state official agencies, there are the State Departments of Health in each state, many of which maintain extensive services; for example, diagnostic laboratory services wherein millions of specimens are examined at state expense, most of these coming from physicians. In the laboratory of the New York State Department of Health there is a staff of over 200. Many states manufacture and distribute biological products such as smallpox vaccine, diphtheria antitoxin, antirabic vaccine, et cetera. They also maintain divisions for the investigation and control of preventable diseases, and for control of the sanitary aspect of water and sewerage systems and of regulating the production and distribution of milk. State Departments carry on in one form or another an educational program, chiefly by way of pamphlets issued free of charge to the people of the state. Practically all of the larger municipalities of the country maintain health departments. These frequently maintain departments for anti-tuberculosis work or venereal disease control; most of them also maintain diagnostic laboratories.

There is of late years an increasing tendency toward the establishment of county departments of health as being the logical unit for the control of contagious disease within the state. It is interesting to note that of the 3,076 counties in the United States in 1929, 1,794, or 58.3 per cent, have one or more hospitals; counties having only special Federal or State institutions are not included.

As this panorama of agencies unfolds before him, the physician constantly reminds himself that they all represent governmental efforts to bring about a universal realization of the promises of health. He reflects that in many of these efforts his services and coöperation are still earnestly solicited, while in others, such as in problems of water supply, sewage disposal, drainage, etc., the important rôle he once played remains chiefly as an historical interest—obliterated by the engineering drama now filling the stage upon which he once played his prophetic evangelical part.

Other agencies, however, are similarly engaged in this universal realization of the promises of health. These are the private or non-official agencies. They are independent. The harmony with which they play their part with the medical profession and official agencies depends upon the purpose and policy of the group, and as such is a variable. Most of them are quite specialized, as is indicated by their names. The mention of some of these groups will be sufficient indication of the quantitative part they now play in public health: The American Public Health Association, The American Red Cross, The American Association for Medical Progress, The American Child Health Association, The National Tuberculosis Association, The American Social Hygiene Association, The National Committee for Mental Hygiene, The American Society for the Control of Cancer, The American Heart Association, The National Society for the Prevention of Blindness, The National Organization for Public Health Nursing; there are the "foundations"—the Rockefeller Foundation, the Milbank Memorial Fund, the Commonwealth Fund, the Duke Endowment, the Couzens and the Rosenwald Funds. With none of these groups has organized medicine coöperated, and none has been taken over by an official agency, although some of their functions have been assumed by official groups. Dr. S. W. Welch, State Health Officer of Alabama, in 1924, said of this group: "Successful unofficial leadership, which wrests from the official agency of health duties legally conferred upon it, can prove only a menace to our Government; and this is no less true when the unofficial leadership enjoys the uttermost confidence of the people and is rich in funds accruing from the benevolence of the people. Profound altruism and devotion to the cause of public welfare on the part of misdirected leadership does not render it benign, nor does a leadership based upon sound scientific principles prove an unmixed blessing if it builds strong human bodies capable of self-control and at the same time breaks down our feeble human attempt to govern ourselves collectively."

If there is a disagreement between these two great types of agencies, the physician finds it difficult to arouse himself to any active partisanship. From them he receives pleas, orders, suggestions, and solicitations for coöperation in routine established matters, in new health projects, in new methods, in "drives," in surveys, and in educational campaigns. He is cajoled, praised, threatened, or ignored.

Irritated somewhat, and uncertain, he turns to his profession. Unquestionably it has, in a century or less, pulled itself out of a welter of ignorance and superstition of an amazing depth; it has wrenched itself loose from all associations with the past, and, on a road of its own making reached the position it now occupies. It has made its own schools and teaching methods and has devised means for their improvement and for defending their standards against those who by digressions and compromise tried to lower them.

He finds that for the United States there are 126.6 physicians for each 100,000 population. Two countries approach this number, Austria with 113.9, and Great Britain with 111.4. France has 58.9, Norway has 56.9, Belgium 53.8, Sweden 34.6; last comes Persia with 2.5.

There are in the United States 76 medical colleges, of which 20 are in three states, New York, Pennsylvania, and Illinois. These 76 colleges graduate annually 4,565, of which only 204 are women, and of which 3,211 have either an A.B. or a B.S. degree in addition to their M.D. degree. There is an annual enrollment of 21,597 students. The number of medical colleges has decreased greatly in the past twenty years. From a total of 100 in 1880, the number reached its peak of 162 in 1906. The decline was abrupt until 1915, when 96 colleges remained. The present number represents the results of a more gradual elimination, largely through the merger of two or more schools into one.

These figures are taken from the 1930 report of the Council on Medical Education and Hospitals of the American Medical Association, in whose Journal they appear. The Council was organized in 1904, and since 1905 has published its annual report in the Journal of the Association. Commenting editorially upon the work of the Council, the Journal remarks that "medical education has shown a tremendous improvement over conditions existing in 1900. . . . Early in its work the Council found that no national supervision or control had ever been placed over either general or professional education, since the constitution of the United States had left such matters to the state governments. With a few exceptions also it was found that the states had not assumed such authority, nor had any supervision or control been provided for educational institutions after they had been chartered. Consequently, the medical schools were multiplied out of all proportion to the increase in population, and by 1900 the United States had about half of the world's supply."

The physician's pride in the feat of his profession raising itself by its own boot-straps is but little diminished by the reflection that it is a constant aim of all groups and classes to do likewise. Prerequisites, ritual, technic, manner—all are in constant use to lend not only worth but exclusiveness and distinction to groups and classes. But when Mencken speaks of "the aloof, philosophical air of a dermatologist contemplating an eczema," he refers to a professional manner which has languished of late; it requires something stronger than "manner" to withstand the winds of publicity set in motion by all the agencies now so actively engaged in helping the cause of health. Increased educational standards as well as a strengthening of organization within the profession, as they become more apparent to him, may seem to the physician as twice blessed. Yet he wonders at the apathetic manner in which the public so often receives his efforts. Can it be that the higher education, as an *ipso facto* vehicle for distinction has become so common as to have lost its magic? Here, however, he is led into questions of educational values as elusive as the orientation for which his search was begun. He can only drop the question with regret.

There remains the content of modern medicine, the nature and quality of its promises. Are they absolute, relative, or only potential—realizable, perhaps, through the operation of some administrative machine of which he shall be a part? Two qualities characterize these promises at the very start, their number and their newness; it follows almost as a corollary that the promises shall be colored, in some degree, by the attributes of newness anywhere; namely, a certain diffidence and an awkwardness in delivery.

The absolute values in modern medical promises are the prevention and treatment of diphtheria, together with an accurate method of testing for individual susceptibility, a method for preventing smallpox, typhoid fever, yellow fever, hookworm, and malaria. A whole series of diseases have become relatively subject to control; this includes tuberculosis, measles, infantile paralysis, scarlet fever, diabetes, pernicious anemia, rickets, the intestinal disorders of infancy, the toxemias and infections of the puerperal state, a considerable number of primarily surgical conditions for which specific surgical procedures will bring relief, a series of endocrine disturbances for which specific glandular therapy is now available. Palliative measures of value are now at hand which even in recent years were unknown; here may be included new drugs and refinements in the manufacture of old ones—the new local anesthetics, analgesics, and sedatives, a whole new series of drugs have become available for intravenous use, thus increasing their potency in emergencies, great refinements in the treatment of fractures, of burns, of heart disease. Here, also, must be included extensive new diagnostic procedures and refinements in old methods; the X-ray, the electrocardiograph, methods for determining the metabolic rate, the significance of changes in the blood cells, a practically new science of blood chemistry. There is a tendency away from surgery as a field in itself towards renewed interest in medical treatment, toward functional study, toward relationships between organs, and of organs to constitution. There has been a tremendous expansion of content and promise in the field of mental diseases and the neuroses, with mental hygiene as an attendant development.

The medical literature already written concerning these subjects is extensive. The newcomer, the occasional wanderer therein quickly loses himself. Yet the physician knows he must either become familiar with its maze, or rationalize himself into contentment outside. Possibly, he feels, it is this tremendous scope and newness of medicine which has contributed as much as has a lack of organization to a certain slowness in bringing the promises to realization on a universal scale. Indeed, this point often enters into discussions of modern medicine. Dewey says: "Ideas formed in the days when it was reasonably possible for a man who had been studiously through the schools to master the sum total of learning too largely control the schools of today."

An idea, expressed by H. H. Moore in his book, "American Medicine and the People's Health," recurs again and again: "The spectacle of human beings enduring suffering and death from diseases which may readily be prevented will appear rather annoying to a citizen of the twenty-fifth century reading for the first time the history of the present age." This, he believes, is due to a lack of adjustment somewhere in the recent evolution of medicine and he considers it as "an example, perhaps, of a social phenomenon, which William F. Ogburn has called 'cultural lag.'" This lag, he believes, expresses itself in the comparatively unorganized condition of the majority of physicians. There is a lag in the development of machinery for the utilization of the promises of medicine. This lack of coordination, however, the physician knows is felt. President Hoover's White House Conference on Child Health is distinctly an effort at coordination.

Numerous specific examples of a slowness in bringing health promises to general use occur to the physician and may be called expressions of "cultural lag" with as much accuracy as they might be termed neglect. Thus, vaccination against smallpox was known even before the time of Jenner (1798), but it is far from being universally practiced today. It was ten years after Behring's discovery of diphtheria antitoxin before our physicians generally made use of it, and even today, with a means for preventing diphtheria at hand, the disease still kills hundreds of children yearly. There was a similar slowness in adopting Pasteur's inoculations against rabies. Sir Humphry Rolleston observes that "unfortunately the art of healing may lag long behind the scientific milestones." He cites the inertia following Harvey's discovery of the circulation of the blood; blood transfusion, though done in the seventeenth century, did not become routine until the Great War; Christopher Wren originated the intravenous injection of drugs, but the general use of this method did not come until 1910, with Ehrlich's arsphenamine discovery; Davy discovered nitrous oxide gas in 1799 and its use as an anesthetic was demonstrated the following year at Guy's Hospital; but the American Lang (1842), Wells (1845), and Morton (1946), with their use of ether, first brought anesthesia into general use. It was forty years after James Lind showed how scurvy could be prevented that the British Navy put his simple remedy into use and banished this ancient scourge. The same lag was apparent after Lister first demonstrated his antiseptic method in surgery. The lag in the fight against puerperal (childbed) fever is a classic example of the medical prophet without honor—even in his own country. The physician's regret at this failing in his profession is not relieved by a similar, and perhaps equally grievous, lag in law, in politics, or in education.

Here again, as at other points in his speculations, the physician must consider the effect of mass. Before he can practice his art, he must somehow give movement to his knowledge, and the difficulty of this effort is in proportion to the mass of knowledge he has accumulated. This explains, in part, the facility with which physicians of even twenty-five years ago practiced their art, the time they had to impress themselves upon a world ready and susceptible to the sympathy and good cheer which sprang, perforce, from minds whose relative dearth of scientific content led them to embrace a priestly instrument as preferable to that of the charlatans'. The physician by no means intends to deride the part of sympathy in the presence of suffering; its rôle, however, while still important, must be filled by a lesser portion of the physician's mind now taken up more and more with critical selection from the range of diagnostic and treatment possibilities before him. Yet much of the criticism directed against him today is less concerned with his mastery of the present content of medicine than it is with his departure from the pleasant, simple ways of the past.

The scope and complexity of medicine have produced another result for which the profession is criticized, no doubt justly. Doctors are said to protect one another, that this mutual *laissez faire* attitude in the presence of mistakes on the part of their colleagues is an anti-social act. The validity of this criticism becomes less certain when this fact of the mass of medical knowledge is realized. To condemn a doctor for slowness in absorbing it, for slowness in giving it movement, for inaccuracy in interpretation, is a difficult thing to do without qualifications; even to detect dishonesty in its use or wilful neglect in its execution is by no means as simple as it may seem. Indeed, the public, in their enthusiastic support of follies in the field of health are guilty of a worse error, since their action reverts to the use of magic and superstition and a discarding of method in the choice of means.

The physician must revert again to education in spite of his ignorance, since the term has appropriated every aspect of intellectual method.

Dewey speaks of the confusion and distraction of modern education in which almost everything "finds its way into 'courses' and textbooks." The task, he says, is to reduce and simplify the course of study. He would cease inculcating information in quantity and offer instead a development of an "independent method of thought and inquiry" by a full treatment of a limited number of typical groups of material. Of education in science he says: "The essentials of scientific method, of a certain way of looking at things and seeking and weighing evidence, in short the development of judgment, are swamped in the acquisition of information, all the items of which stand on the same level and are equally subject to belief or unbelief. The mind is left more ready to seek for signs and wonders, and more ready to grasp at and swallow whatever is presented in print. The mere mass of what is offered daily, monthly, and yearly, overpowers independent judgment and creates a state of intellectual impotence; the mind is oppressed rather than enlightened." Here, he says, signs of improvement may now be found in professional education which "simplify not by arbitrary limitation to traditional portions of the field, but by emphasis upon subject matter that is strategic in developing command of method." He finds failure in "fundamental intellectual achievement" due chiefly to two traits: "undue deference to anyone who obtains popular prestige as an 'authority' in any field, and an accompanying credulity of mind that undiscriminatingly accepts for a time anything offered, only to turn soon to some newer topic." The physician readily discovers these traits not only in himself and in his profession, but with especial clearness in the recent efforts of organized medicine to educate the public in matters of health. To a large extent, many offsprings of this effort as reflected in individual and social response, often made with a certain aplomb as having a sound "scientific" basis, are the opposite of scientific. In his Grammar of Science, Karl Pearson says, "The classification of facts and the formation of absolute judgment upon the basis of this classification—judgments independent of the idiosyncrasies of the individual mind—essentially sum up the *aim and method of modern science.*" He describes the function of science as "the classification of facts, the recognition of their sequence and relative significance."

At times, when the physician sees to what an extent special moral and commercial connotations are mixed with the promises of health he wonders how the contamination is achieved with so little comment. His reaction to a recent article in Harper's on the superstitions of southern negroes in obstetrical matters was to reflect how largely a similar folly possesses and guides many college graduates in northern white people. He turns now to another statement of Pearson's, "Modern science, as training the mind to an exact and impartial analysis of facts, is an education specially fitted to promote sound citizenship."

At once, it seems, the whole question becomes simpler—not of solution, perhaps, but of description. It is no longer a vague, restless disturbance, but a definite condition having definite causes and immediate results quite reasonable in the sequence as it has so far revealed itself.

The physician feels that his desire for orientation is shared by educators, statesmen, sociologists, and economists—by everyone, indeed, who is trying to understand those swirls and eddies which are caused by the sudden influx of new ideas and new forces into the quiet pool of society: not the least of the forces involved being the inertia of society itself, now grown to vast proportions through mere quantitative increase in bulk. He recalls Osler's statement that the introduction of quinine was one of the most powerful forces in our present civilization.

With all the others, then, the physician feels that he must turn to the task of arranging his material, of developing skill in the use of the scientific method, of clarifying and simplifying the promises of health. If he finds that others are using the same tools in the solution of their difficulties he feels that there will be less and less need for the growth or even existence of many of those large intermediary groups whose interpretive and administrative functions now seem so necessary. Patience, if not evoked, is imposed by circumstances, and as such becomes a burden and a punishment rather than an aid.

Here, then, is a field in which his utmost industry may be employed. If society will understand his task they will make it easier by not requiring him to defend it from the intrusion of methods which, as they now command no respect from his own profession, will then inspire none from society upon whose ignorance they now maintain their saprophytic life.

Havelock Ellis, in discussing some observations of Jules de Gaultier on the artist, said: "If he seeks to mix himself up with the passions of the crowd, if his work shows the desire to prove anything, he thereby neglects the creation of beauty. Necessarily so, for he excites a state of combativity, he sets up moral, political, and social values, all having relation to biological needs and the possessive instinct, the most violent of ferments." The physician feels himself respond to this view. Like the artist, he hopes that "by revealing the spectacular character of reality he restores the serenity of its innocence."

BISMUTH IN THE TREATMENT OF SYPHILIS

In the selection of a bismuth preparation the different factors come up as to whether one wants a soluble or an insoluble preparation, how often the dosage is going to be given, and how rapidly it is desired to have the preparation absorbed. The average effective bismuth preparation should contain from 0.03 to 0.2 Gm. of metallic bismuth in a dose and a course of therapy lasting eight to ten weeks should probably amount to from 0.6 to 2 Gm. of metallic bismuth. The Council on Pharmacy and Chemistry has gone on record as opposed to intravenous bismuth therapy. The therapeutic dose is too close to the toxic dose; therefore one is limited to intramuscular injections. If one is desirous of a preparation with comparatively rapid absorption and one that probably should be given twice a week, one might employ the thio-bismol in a dose of 0.2 Gm. (metallic bismuth, 0.075 Gm. per dose); or the potassium sodium bismuth tartrate, aqueous solution, usually with a dose of 0.1 Gm. (metallic bismuth, 0.04 Gm. per dose). These soluble preparations should be given twice a week and are hardly suitable for general office practice. When one administration per week is feasible only, one is forced back on the use of a soluble preparation suspended in oil, or an insoluble salt suspended in oil. Recently, there has been a turn to the use of liposoluble bismuth preparations; there is a claim that these combine the good points of both the soluble and the insoluble salt, but it is too early to answer this question definitely. (Jour. A. M. A., May 16, 1931, p. 1721.)

THE INSTITUTIONAL CARE OF TUBERCULOSIS*

H. A. Burns, M.D.
Superintendent Minnesota State Sanatorium
Walker, Minnesota

THE approach to a consideration of the function of the modern sanatorium in the tuberculosis program must recognize first the background, historical and social, out of which the institution has evolved. Secondly, we must evaluate the sanatorium's success in adjusting itself to new conditions as experience and research guides us ever closer to the ultimate control of tuberculosis.

While the hospital is a human institution as old as recorded history, in its modern setting it is one of the later developments following the intellectual revival in Europe. During the eighteenth century, the hospital became of recognized importance in the larger cities. During the middle of the last century, the first special hospital for the cure of tuberculosis was put into operation. At a time when tuberculosis caused one-seventh of all the deaths in Germany, Herman Brehmer in his doctorate thesis of 1853 maintained that tuberculosis was a curable disease, basing his conclusions upon the frequent observation of healed lesions at autopsy. Brehmer established the first successful sanatorium in the world in 1859.

Because of the many and confusing symptoms of pulmonary tuberculosis as shown by percussion, auscultation, palpation, and by the surgical forms of the infection, this disease early stimulated the greatest clinicians in the profession to its study. The special hospitals for the tuberculous gave the followers of Bayle, Laennec, Villemin, and Auenbrugger an opportunity to apply their teachings relative to diagnosis and physical findings. Treatment was given more prominence in the physician's attitude to the patient following the advent of the special hospital and still more as a result of the discovery of the tubercle bacillus by Koch in 1882.

There are few, if any diseases, that have caused nearly the number of tragedies in family life as tuberculosis. For many centuries and in all nations this wasting disease has been rather definitely identified and feared. There is every reason then that as soon as men suspected it possible to discover the nature of tuberculosis many workers would become interested in the search for more knowledge concerning this devastating disease about which a vast field of information suddenly became available for the physician's use. Because of the marked nutritional disturbances and its chronicity, the clinical symptoms were given much attention, while other phases of the problem were allowed to remain unnoticed.

One of the early misfortunes in the institutional care of tuberculosis was the change of the tuberculosis hospital into a sanatorium. After some twenty years, we are now trying to salvage as much as possible of the sanatoria that tuberculosis hospitals may survive. There is a drift even now towards the inclusion of the tuberculosis patient in the general hospital, and it is conceded that with the establishment of a proper technic there could be no public health opposition.

The institutionalization of wards of the State while of ancient origin became prevalent during the early part of the last century and grew rapidly until the period following the World War. The State has attempted in the past to institutionalize its penal, domiciliary and therapeutic dependents. Because of the economic burden imposed upon the taxpayers by this increased load, the necessity of limiting the multiplication of institutions has become apparent.

The preventorium as an adjunct to the sanatorium in the care of the tuberculous can be largely, if not totally, eliminated by adequate supervision by the public health nurse of the child in the home. Many of the cases of adult tuberculosis where the individual is mentally, economically, and emotionally equipped to coöperate with the family physician and the field agencies can be given at least as effective care outside the sanatorium as can be given inside. Before these changes can be adequately established, the field service must collaborate with the sanatorium physicians in turning over under their supervision the therapy of selected cases among the tuberculous to the family physician.

---

*Presented before the Lymanhurst Medical Staff on December 11, 1930.

There are three individuals who should be concerned in the care of the tuberculous: the family physician, the epidemiologist, and the sanatorium physician. The maximum social results in terms of prevention and cure will not be accomplished until these three are brought together with a sustained medical interest and responsibility throughout the period of their medical supervision.

Early in sanatorium work in this country, there was a very definite and a very unfortunate separation of the two fundamental elements which together should compose the tuberculosis hospital.

One school espoused the clinical importance of the sanatorium and insisted that the institution served no other purpose than the treatment of the individual case. This school was unconsciously attempting to induce the governmental unit creating and supporting the institution to foster "State Medicine."

Considerable evidence in support of this statement has developed from time to time in many sanatoria. However, the return of the sanatoria to a hospital status has made it possible for the physician in tuberculosis work to coöperate with the general practitioners and the specialists. He now becomes one of a partnership whose business it is to care for the sick.

The second group considered that the institution should be primarily for the removal of the infected and infecting individual from the home, and that the institution was created primarily to serve a purpose in preventive medicine.

The clinical point of view won out, and for twenty years preventive medicine has been pleading, usually to locked doors and deaf ears, to apply the same epidemiological methods to tuberculosis that have proven so effective in the control of most of our infectious diseases.

One of the most hopeful tendencies at this time is that during the past few years there has been demonstrated in many quarters an expression of friendliness between these two opposing groups, an apparent desire to get together in the proper management of this problem of tuberculosis control. We now concede that from a public health point of view the sanatorium is an adjunct to the epidemiologist primarily, and to the clinician secondarily. The modern institution for this reason cannot operate successfully and effectively without coördinating its clinical work with its field service. A well-balanced sanatorium must function in the field as effectively as it does at the bedside in the institution. The final coordination of these two activities will accomplish what either alone can never do.

The sanatorium, as its name implies, has unfortunately divorced itself from the hospital, and now for various reasons it requires a hospital status to bring to its tuberculous patients the advantages of modern medicine. Where isolation was once a requirement, consultants in many specialties are now sought. Where one doctor was required to serve as a care taker, now a corps of well trained physicians are essential. Where fresh air was given afar off to insure purity, purified and conditioned air can be obtained at any place desired. Sunshine can be given twenty-four hours daily. Altitude and season are of little importance so long as you have a lamp and a wall plug.

It was but a short time ago, and some of the textbooks still inform us that in the selection of a sanatorium site one must choose protection from the prevailing winds, and it must be located on sandy well drained soil removed from congested districts where the atmosphere might be charged with dust. These elements considered of most importance but fifteen years ago are very distinctly of secondary importance today.

Our sick tuberculous patients are not in search of seclusion or a home. They want treatment and maximum recovery in the shortest possible time. To render the patient the service required, we must vacate the sanatorium and enter the tuberculosis hospital.

The evolution of the hospital since the days when the sick were laid in the precincts of the temples of Greece and Egypt had not changed greatly prior to the middle of the nineteenth century, when the etiology of disease was attracting the attention of the medical profession, and the special hospital was emerging from the old general hospital. The modern hospital, while elegant in exterior, furnishings, and equipment, has not in some instances changed greatly from the general hospital of a century ago.

The most outstanding similarity is perhaps the lack of a contagious technic. With the development of the special services in the modern hospital, we have an aseptic technic in the operating and delivery rooms and a special technic for the contagious ward. We have no protective routine for the new or unknown case that is as dangerous and possibly more so than the one diagnosed and under treatment.

The tuberculosis sanatorium is a development of the specialization in hospital care of the sick. There has been much added to the original sanatorium, but like the modern hospital it has also failed to establish a protecting technic. A nurse trained in contagious technic would be unable to work in the present day sanatorium because the contagiousness of tuberculosis is not recognized in the set-up of the institution.

The educational and training facilities in the sanatorium have been neglected. Only recently have some of the sanatoria located near medical centers developed in a moderate way the training possibilities within their possession. The sanatorium too often has considered itself a closed staff and its nursing service of secondary importance. Every sanatorium should offer training to pupil nurses in both bedside care and field nursing. In a general way the ex-patient, physician or nurse should not be employed in sanatorium work, since they have made an adjustment to the type of institutional work which will make the fewest demands upon their time and energy. Efficient medical and nursing care calls for energetic and physically strong workers, who are interested in developing and maintaining an association among patients and employees that will in no way endanger either.

The staff of the sanatorium too often isolate themselves from the profession and complain about the lack of the coöperation they receive. The tuberculosis hospital should encourage clerkships and junior staff members whose residence is a part of their preparation for practice. This contact with the profession will benefit the sanatorium, the profession, and most of all the medical staff of the sanatorium.

A fundamental change in sanatorium administration involves the extension of a contagious technic throughout the institution. The tuberculosis sanatorium should be remodeled. It must treat rather than tolerate sick people. It must train many of them to live as "carrier cases" in their communities and homes and to live so as not to endanger others. The tuberculosis hospital must be staffed by highly trained physicians and nurses trained both in treatment and preventive medicine. The field work must be recognized of as much importance as the hospital. There can be no rest hours, and there can be no pension positions for part-time employment in these services.

The educational facilities offered patients in the sanatorium of the past have been altogether inadequate from an epidemiological point of view. The occasional talk by the physician and the cursory reading of health books and journals by the patients does not often aid in the development of new health habits, unless they can be repeated and rehearsed in the institution and continued under nursing supervision after discharge.

We acknowledge the fact that there is a considerable variation in the virulence of tubercle bacilli, yet our attempt to educate the patient to the danger of reinfecting himself with a more virulent strain of the organism is never considered. The sanatorium frequently employs the positive-sputum patient, sometimes even as a food handler. The danger of reinfecting a group of patients is more serious possibly than giving the initial infection to a group of well people.

We do not know just what the danger may be as a result of this type of contact, but we know that it has possibilities that should not be ignored. All dishes should be sterilized and each patient should be taught to carry out as far as possible a contagious technic in his contact with fellow patients. The criticism at once arises that we would make neurasthenics out of our patients. Possibly, but more certainly we shall make them safe, and we shall increase their chances for recovery.

Most patients have a determination to recover which too often is interpreted as being the optimism of the tuberculous. This "will to recover" is a power in the hands of the physician. Education and information in a very great measure replaces discipline. The "will to recover" is seldom emphasized, yet it, rather than contentment, is and must remain the greatest single aid to every hospitalized man or woman who is ill with pulmonary tuberculosis. The sanatorium was created to provide for the patient an environment in which contentment was a dominant factor. The tuberculosis hospital's interest in the patient's attitude centers upon his "will to recover."

CONCLUSIONS

The tuberculosis hospital is a teaching, a therapeutic, and a prophylactic institution, while the sanatorium has been and still remains largely a domiciliary and a therapeutic institution.

The training of patients to live outside of the institution without endangering others is a public health necessity which if carefully developed would result in the discharge of many cases now occupying hospital beds while receiving domiciliary care.

The family physician, the institutional physician, and the epidemiologist working together will bring as good treatment to the tuberculous as they have received in the past from the institutional physician alone. Through this coördinated medical effort material progress will be made to reduce in number our cases approaching an eventual breakdown. This association will make possible the care of many patients at home or in local general hospitals who now remain neglected. We will bring the tuberculosis problem under general medical supervision and control, a condition which can never be realized if the disease continues to be considered an institutional problem alone.

Our great task today is to save the tuberculosis sanatoria from themselves. Hope in the future lies in a group association including the family physician, the epidemiologist, the clinician, and the nurse both in the institution and in the home. It must be through these new alignments in our measures of treatment and control that will give us a chance to salvage all that is good of the present day sanatoria and from it produce the tuberculosis hospital. It is our opportunity now to make a contribution to preventive medicine that will mark the genesis of a new day in tuberculosis control.

MAGNETIC BELTS

The Council on Physical Therapy reports on the "Vitrona" and "Theronoid," stating that during the past four or five years there have been exploited to the public under various names solenoids for use in connection with the house electric light circuit, for the alleged purpose of curing or alleviating human ailments by means of magnetism. The Council points out that the original device of this kind was the "I-on-a-co" and that two of the most widely advertised and extensively pushed imitations of the I-on-a-co are, respectively, the "Vitrona" of the Rodney Madison Laboratories, Inc., and the "Theronoid" of the Theronoid Corporation. The Council describes the construction of these outfits and discusses the claim that the apparatus will magnetize the iron in the blood and that such magnetization will bring about the cure of many diseases and conditions. The Council states that it has been known for a half-century or more that magnetism has no demonstrable effect on the human body and its processes. Because of many inquiries received, the Council carried out experiments with the Theronoid and Vitrona. Independently, A. J. Carlson carried out experiments and found that the Vitrona produced no effect of energy metabolism. Other experiments were carried out all of which demonstrated that the Vitrona produced no effect on the human organism within the influence of the coil. Similar experiments with the "Theronoid" showed that absolutely no absorption of power by a human subject surrounded by the Theronoid could be detected. (Jour. A. M. A., May 16, 1931, p. 1693.)

TUBERCULOSIS OF THE ANUS AND RECTUM*

Charles K. Petter, M.D.
Senior Resident Physician, Glen Lake Sanatorium
Oak Terrace, Minnesota
Walter A. Fansler, M.D., F.A.C.S.
Consulting Proctologist, Glen Lake Sanatorium
Minneapolis

TUBERCULOUS lesions in and about the anus and rectum, though constituting a comparatively small part in the vast field of tuberculosis, are of sufficient importance to warrant special consideration. While tuberculosis, as a disease, manifests itself usually as a pulmonary lesion, the possibility of its affecting any organ or tissue must not be overlooked. Therefore in every case of phthisis one should take a history specifically covering symptoms referable to the anus and rectum (pain, swelling, bleeding, discharge); likewise the physical examination should not be limited to the part manifestly affected, but should be general, including proctoscopic.

The tuberculous lesions which one finds in the anus and rectum are not numerous, and, with exceptions which will be mentioned, are just as amenable to treatment as lesions elsewhere in the body. They can be divided, roughly, into two groups, as follows:

1. Perianal cutaneous tuberculosis.
    a. Miliary tuberculosis of anal skin.
    b. Tuberculosis cutis orificialis.
    c. Lupoid cutaneous tuberculosis.
    d. Tuberculous anal ulcer.
2. Perirectal abscess and fistula in ano.

Tuberculous ulceration in the rectum itself is not included in the present discussion because it always occurs as part of a more general intestinal tuberculosis, and therefore does not present a true proctologic problem, but one for the gastroenterologist.

Miliary tuberculosis of the anal skin occurs in conjunction with acute general miliary tuberculosis, which is highly virulent and rapidly fatal.

Tuberculosis cutis orificialis occurs in the mucous membrane and adjacent skin of patients who have no resistance to tuberculosis, and has been encountered by us in adults who are in extremis.

The lupoid forms occurs as a subcutaneous nodule covered by healthy but slightly bluish skin, and is seen in patients who have a manifest resistance to tuberculous infection. This lesion is diagnosed on biopsy. In some cases it may go on to central necrosis with resulting ulcer formation. Surgical removal or destruction with actual cautery, followed by ultra-violet radiation, gives very satisfactory results.

Table I

PROCTOLOGIC FINDINGS IN A GROUP OF 190 MALE PATIENTS ON ADMISSION TO THE SANATORIUM

NORMAL	52	27%
PATHOLOGIC CONDITIONS	138	73%
Int. Hemorrhoids	94	
Cutaneous Hemorrhoids	34	
Hyp. and Inflamed Anal Papillæ	21	
Anal Fissure and Ulcers	13	
Fistula in Ano	13	
Scars of Operation (abscess, fistula)	4	
Thrombi Ext. Hemorrhoids	8	
Peri-rectal Abscess	1	
Stricture of Rectum (Injury)	1	

Total of 189 Lesions in 138 Patients

The so-called anal ulcer, we feel, is a definite clinical entity and its evolution can in most cases be easily followed. For example, a patient may complain of definite pain and possibly some bleeding at the time of defecation. This leads us to suspect a simple anal fissure, and examination reveals the presence of such a lesion. Then, after a week or so if the fissure is not treated, the patient continues to complain and examination then shows a ragged, indurated, fiery red ulcer at the site of the previous simple fissure. Records of the case reveal that this patient has a decided positive sputum or active intestinal lesion, which has been the source of infection of the fissure.

We have found the best treatment for these lesions to be section of the external sphincter, followed by destruction of the diseased tissue with the cautery. Daily applications of heat and ultra-violet irradiation, hasten healing of the operative wound.

---

*Read before the Clinical Section, National Tuberculosis Association, at its annual meeting, Memphis, Tenn., May 10, 1930.

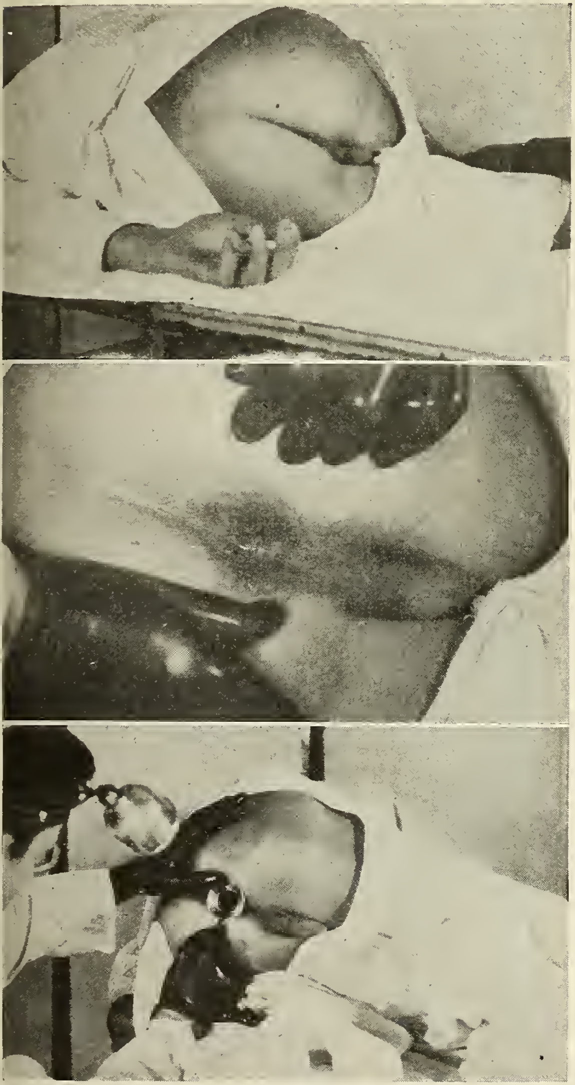

Fig. 1. Patient in Sims position renders adequate external and proctoscopic examination easy.

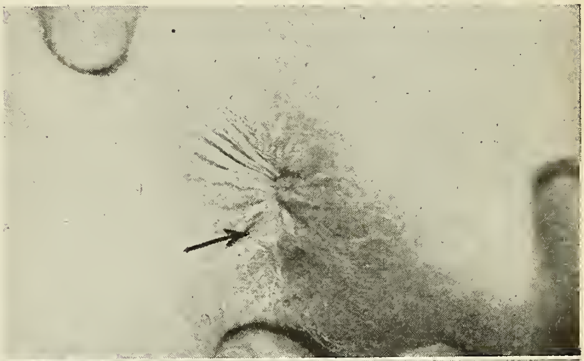
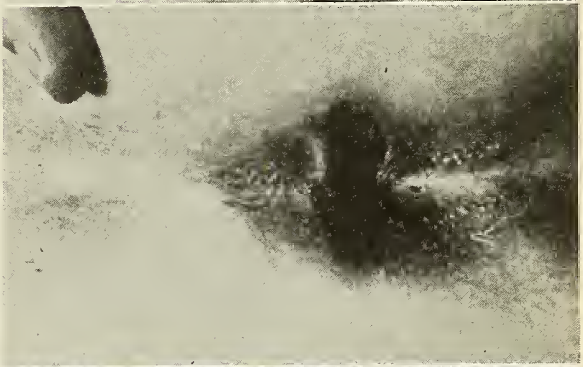
In the examination of 551 patients we have encountered twelve cases of tuberculous anal ulcer, two cases of tuberculosis cutis orificialis and one case of the lupoid form.





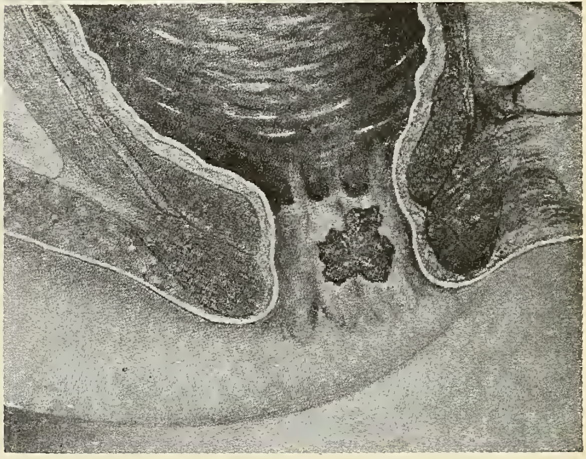


Fig. 2 *(Top)*. Lupoid tuberculosis of peri-anal skin.
Fig. 3 *(Center)*. Tuberculosis cutis ani.
Fig. 4 *(Bottom)*. Tuberculous anal ulcer.

Perirectal abscess and fistula in ano really constitute a single topic, for fistula is the result of an untreated or improperly treated abscess. Perirectal abscesses develop from infection in an anal crypt. The crypt becomes inflamed, sealed over and the infection burrows into perirectal tissues and eventually ruptures through the skin or less frequently back into the bowel. The usual history in a case of this type is about as follows: the patient notices some soreness about the anus, then after a few hours a painless swelling adjacent to the anus. As time goes on this mass enlarges and frequently becomes very painful be-

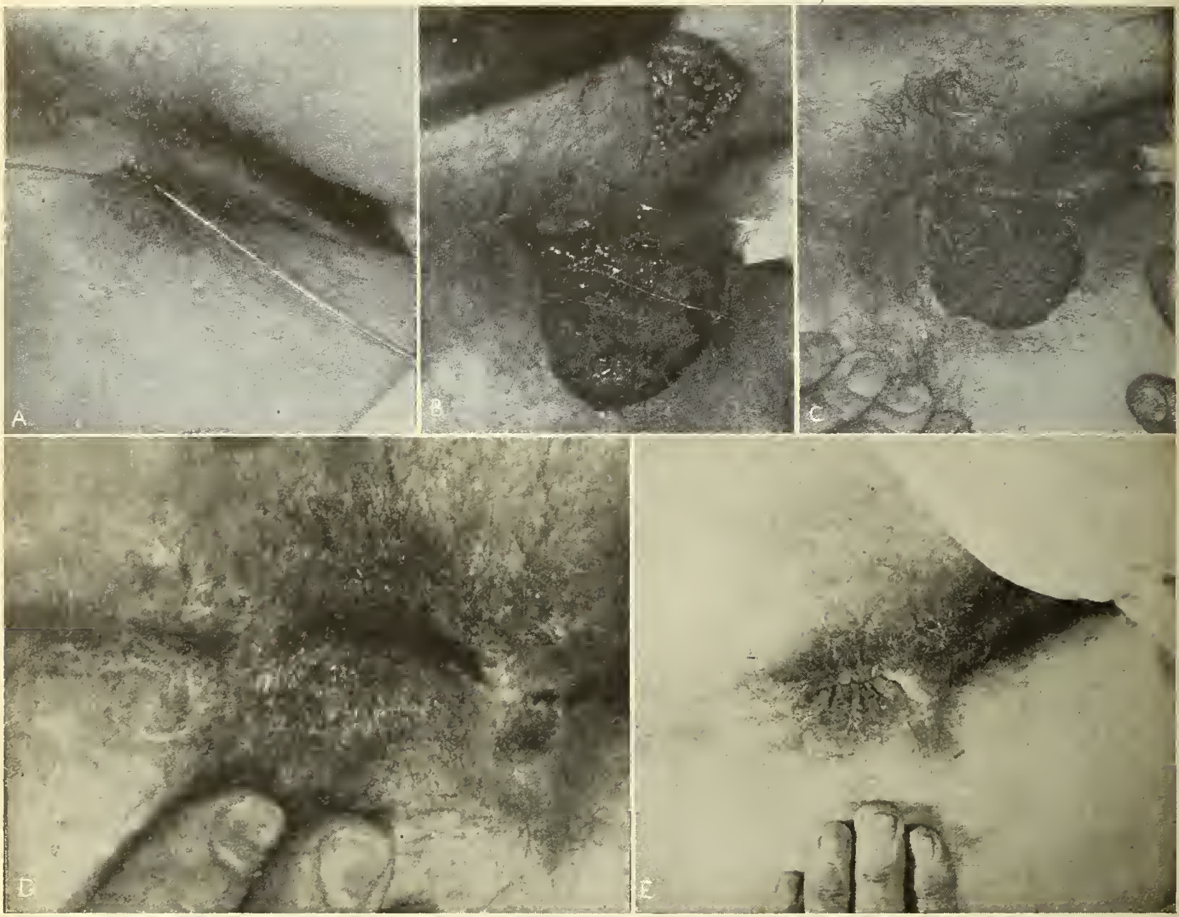

Fig. 5. A typical abscess and its treatment. (a) Marginal abscess. (b) Overlying skin removed. (c) After curettage and cautery. (d) Three weeks postoperative. (e) Healed, six weeks postoperative.

fore it ruptures or is lanced. The resulting fistula then follows one of two courses, until operated, namely, it continues to increase in size, with increasing numbers of sinus tracts, or it may go through alternating periods of closing over and breaking down.

Whether it be an abscess or the resulting fistula which one is called upon to treat, the procedure is essentially the same, that is, to dissect out all abscess cavities or fistulous tracts, to demonstrate if possible the opening into the bowel, and to dissect it out as well. We have obtained good results in our series by cauterizing the abscess cavities and fistulous tracts thoroughly with the actual cautery. This applies as well to the opening into the bowel. Remember, the internal opening into the bowel must have been present in order that the abscess could form, but it may be closed at the time of examination. Also remember that the internal opening always occurs in an anal crypt.

Very frequently one is compelled to perform two or more operations before an extensive abscess or fistula can be properly remedied, and this is one reason why surgeons frequently frown on a case of fistula in ano.

Table II

ANO-RECTAL TUBERCULOSIS LESIONS FOUND IN A GROUP OF 320 RESIDENT PATIENTS REFERRED BECAUSE OF ANO-RECTAL SYMPTOMS

	Male	Female	Total
Peri-Rectal Abscess	11	10	21
Fistula in Ano	10	2	12
TBC. Anal Ulcer	1	0	1
TBC. Cutis Ani	1	0	1
TBC. Proctitis	0	1	1
Total	36 or 10%		

From previous work we have found peri-rectal abscess and fistula in ano in 6% of 1,500 tuberculous patients whose records were examined.

The post-operative care of these lesions demands much of the patience and time of the physician. It is essential that the wounds be kept wide open and compelled to heal by granulation for if the edges come together, further fistulous and sinus tracts are prone to develop. We have found the hot sitz bath or infra-red lamp of definite value in hastening the process of repair. Ultra-violet irradiation is a valuable adjunct because of its stimulating action on healthy tissue and its probable specific action on tuberculous disease.

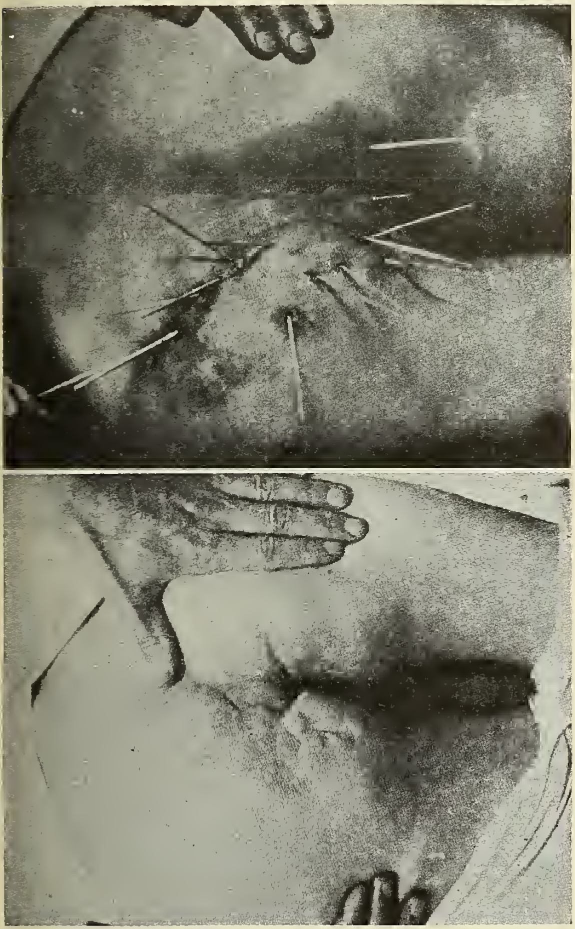

Fig. 6. *(Above)* An extensive fistula. *(Below)* After surgical treatment as outlined in text.

It has been our privilege to study 101 cases of abscess and fistula. From this study several important facts have been learned.

The "proof of tuberculosis" is often quite a task. Smears of exudate are not reliable nor are guinea pigs inoculated with the exudate wholly dependable. We have found that a combination of three laboratory procedures gives us a reliable "proof of tuberculosis." These are: (1) exudate in guinea pig; (2) macerated tissue in guinea pig; and (3) tissue section. Frequently tissue section will show a histologic picture of chronic inflammation, but no tubercle formation, and a piece of the same tissue macerated or suspended in formal saline and injected into a guinea pig will show definite evidence of tuberculosis.

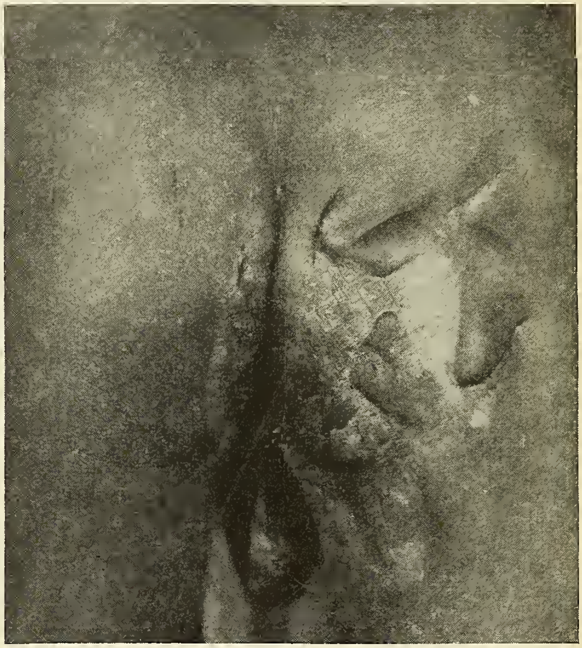

Fig. 7. The result of proper surgical treatment of an extensive fistula.

Table III

CLASSIFICATION OF ANO-RECTAL TUBERCULOSIS LESIONS

1. Tuberculosis of Perianal Skin:—
    A. Miliary Cutaneous Tuberculosis.
    B. Tuberculosis Cutis Ani.
    C. Lupoid Tuberculosis.
2. Tuberculous Anal Ulcer.
3. Tuberculous Proctitis.
4. Tuberculous Peri-rectal Abscess and Ano-rectal Fistula.

When should one treat a fistula or abscess surgically, in the tuberculous patient? Certainly one would not attempt a surgical procedure unnecessarily when a patient is acutely ill. We have found the best policy to be as follows: (1) drain abscesses as soon as they point; (2) keep fistulæ open to prevent burrowing, and then (3) perform radical operation when the patient's general condition warrants it. We do not feel that anything is to be gained by undue delay in operation.

By cleaning up a lesion surgically it is our opinion that the body is relieved of one extra focus of disease, and we have noticed general improvement in the majority of our patients so treated.

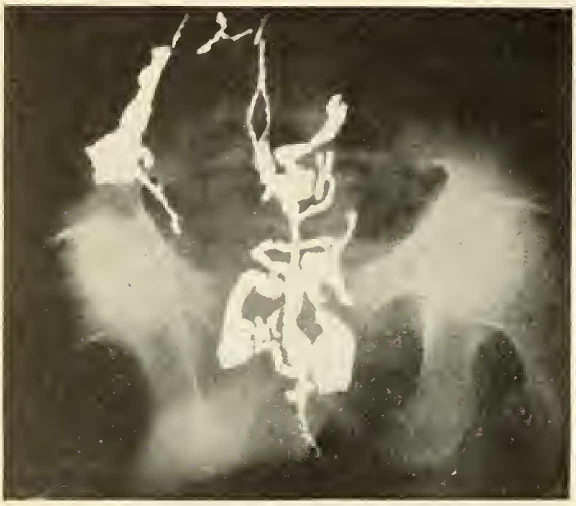

Fig. 8. The end-result of a recurrent peri-rectal abscess which was lanced every two or three years over a long period of time; ramifying sinus tracts all through pelvic fascia.

Positive sputum was present in all but five of our series, and an active enteritis existed in ten.

Table IV

THE SUMMARY OF OUR RESULTS WITH PERI-RECTAL ABSCESS AND FISTULA IN ANO IN 101 CASES

Cases Observed—101
Cases Proven Tuberculous—80—80%
Cases Inadequate or no Laboratory Work—21—20%
Cases Operated—78
    Proven Tbc—70—90%
    Inadequate Laboratory Work—8—10%
    Healed—65
    Healing (Recent Operation)—5 } 90%
    Dead—8—10%
Cases Not Operated—23
    Proven Tbc.—10—43%
    Inadequate or No Laboratory Work—13—57%
    Healed—8—35%
    Dead—15—65%

In tuberculous individuals we have observed perirectal abscess and fistula in ano in 5.8 per cent.

Of the seventy-eight cases undergoing operation, far advanced pulmonary lesions existed in fifty-seven; moderately advanced lesions in eleven; incipient lesions in five; bone lesions in two; and in three we were unable to demonstrate any evidence of a tuberculous lesion elsewhere in the body. The results in the seventy-eight cases treated surgically show 90 per cent healed and 10 per cent unimproved or dead; while those cases which for various reasons were not subjected to operation showed 35 per cent improved or healed, and 65 per cent unimproved or dead.

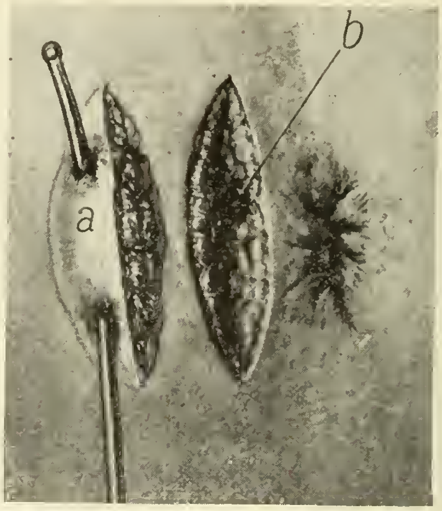

Fig. 9. One reason why fistulæ frequently do not heal after operation. Section (a) removed, but (b) the sinus to anal canal overlooked.

CONCLUSIONS

1. Tuberculous lesions about the anus and rectum occur secondary to a focus elsewhere in practically every case.

2. In our present series of cases perianal tuberculous skin lesions were found in 0.8 per cent of patients observed.

3. Perirectal abscess and fistula, in the same group, occurred in 5.8 per cent.

4. The more common types of perianal skin tuberculosis can be healed if properly treated.

5. Perirectal abscess and fistula in ano in the tuberculous patient present a typical history and clinical picture, and are undoubtedly all tuberculous in origin.

6. Properly treated surgically, these abscesses and fistulæ will heal in at least 90 per cent of cases; neglected, not more than 35 per cent become quiescent.

7. Surgical removal of these lesions relieves the body of the added work of trying to heal an additional tuberculous focus.

CARCINOMA OF COLON AND SIGMOID*

F. C. Schuldt, M.D.
Saint Paul

The one outstanding destroyer of human life, the cause of which has so far baffled medical science, is cancer. I have therefore chosen one phase of this disease as the subject of my address and shall take up carcinoma of the colon and sigmoid, dwelling upon its etiology, diagnosis and operative therapy.

I hesitate to add to the already voluminous American and European literature on the subject, but it is by repetition that impressions are formed. I shall base my remarks on five colon resections performed on four patients.

The proponents of preventive medicine are forever preaching to the laity the importance of recognition of early signs and symptoms. We read the admonition and subscribe to the doctrine. But too often a patient comes to us with more or less definite symptoms which have existed over a period of months and we advise a long period of observation before we consider the condition serious. It is unfortunate that the history of the patient so often reveals such an enduring patience with distressing symptoms both on the part of the patient and the physician. Tennyson said: "Knowledge comes but wisdom lingers."

ETIOLOGY

The cause underlying carcinoma of the large bowel is of course the cause of carcinoma found anywhere in the body. Rankin says: "Without an understanding of the etiology of carcinoma, one is wise to avoid attempting to explain the reason why in one place the disease is found comparatively frequently and in another infrequently."

Considering the duration of symptoms before a patient seeks relief or before the condition becomes alarming, we must draw the conclusion that we are dealing with a slow growing tumor. Turner pronounces carcinoma of the colon low in the scale of malignancy.

It is through the lymph terminals of the villi of the small intestine that the chyme is absorbed. The function of the cecum and ascending colon and a portion of the transverse colon is absorption of fluid from the liquid feces. The lymphatic system here is not nearly so extensive and metastases rarely occur.

The colon of the left side is mainly for storage; consequently the need of lymphatics here is negligible and we find a very sparse distribution of lymph nodes in the mesentery of the left portion of the transverse colon, descending colon and sigmoid. Due to the fact that there are very few lymphatic vessels, metastatic extension is unlikely and if it does occur is slowly progressive but is more likely to occur than on the right side.

Constipation is included among the causative factors, but in a careful history of a carcinoma patient the constipation is usually a consequence, not a cause.

Hayden and Shedden state that: "Constipation is so common an ailment that it can hardly be considered as an important etiological factor."

Schmidt and Von Noorden make the postulate that: "Every case of constipation in the carcinoma age should be suspected of carcinoma."

Kauffmann, commenting on this, says: "This does not work out in practice, since the percentage of carcinoma among the big array of constipated patients is negligible."

The physiology of the colon indicates that the fecal mass becomes firm in the transverse colon and hard in the descending colon and sigmoid. Polya says: "The mechanical irritation of hard dry masses impinging on the lining of the descending colon could be a causative factor." Physiology and roentgenology teach us that the descending colon rarely harbors feces long; it is merely a passageway. The cecum, receiving only liquid feces, is not subjected to this possible etiological factor.

Rankin briefly disposes of the relation of diverticulitis to carcinoma, saying: "Probably it is incidental rather than actual." Is it possible that the anatomical sphincters of the colon are a provoking cause for carcinoma? Multiple sphincters have been described. Opinions vary as to where the sphincters are. Lane declares one sphincter each in ascending colon, transverse colon, splenic flexure, descending colon, sigmoid and rectum. While Balli describes rather completely the sphincters of the colon, he designates three sphincters to the cecum and ascending colon, one each to the transverse colon, splenic flexure, colo-sigmoidal junction and in the terminal colon between sigmoid and rectum. There are no sphincters in the descending colon. Therefore the fecal mass does not remain long in the descending limb. A barium enema will soon leave this portion of the bowel while in a barium meal we rarely can visualize any content in the normal descending colon. True, the mass has been dehydrated and sometimes hard, but it passes through the left limb as if its only function were to provide an avenue for the mass to the sigmoid.

A possible forerunner to a cancer should be considered. Schmieden and Westhues, from the University Clinic of Frankfort, Germany, report on thirty-five cases of colon carcinoma, and in a comprehensive article review the much debated theory of the etiology of carcinoma origin from polyps. They classify polyps into three groups: (1) benign; (2) benign, some becoming malignant; (3) malignant.

Schmieden and Westhues were able to prove that of twenty-eight cases of cancer of the colon with operation sixteen had their origin from polyps. They came to this conclusion in that they either could demonstrate directly that the existing carcinoma had by configuration its origin from a polyp or that in the near vicinity to the existing carcinoma were other malignant polypi. This work of Schmieden and Westhues was corroborated by Aschoff. The grouping of the polyps depends on the differentiation of the cells in the polyp and their staining qualities. The cells of the glands stain much darker in group three and the epithelium is higher, while those in group one which are benign stain lighter. They state that a long pedicle does not determine the grouping, as a long pedicle polyp may fall into either group. "Adenomatous polyps constitute the most dangerous predisposing factor in the development of adeno-carcinoma," says Hayden and Shedden.

Schmieden and Westhues report that on careful examination of resected segments additional polyps were found at times in great numbers, and they make the claim after an extensive study that inflammation is important in the etiology of polyps.

SYMPTOMS

The attitude presented in the history of the average patient is very often too optimistic about the gravity of his symptoms. Patients make light of a colicky pain of the past week or month, or, they say: "For the past month I have not been as regular as I used to be." In the light of knowledge one would say that at that time there may be present, with only such meager symptoms, an annular or cauliflower tumor in the left colon which may have existed for six months and is showing evidence not of a beginning, but rather advanced pathology.

Kauffmann puts it in these words: "Palpable tumor, colic, obstruction signs, microscopic blood and mucus in the stool are not early signs."

Rankin says, "Loss of weight, cachexia and dehydration are not symptoms of primary cancer, but of the metastases." So, among the early signs, remain only slight bowel irregularities and indefinite pain in the abdomen not related to food intake, activity, or time of day. Truly a meager program to work on. Similar colic on previous occasions, due to indiscretion in diet, will be remembered by the patient and he hopes to be better tomorrow. So weeks linger. As the tumor progresses its location becomes indicated.

Carcinoma in the cecum and ascending colon will produce a most profound anemia, a palpable tumor in the right abdomen and rarely obstruction. Tumors of the left side of the abdomen are not accompanied by anemia but by gradually increasing obstruction. Usually such patients eat well, but find themselves using every form of laxative.

Kohn says: "When the cancer involves the colon the symptoms are not ordinarily significant of the disease itself, and it is often difficult to make a diagnosis." The symptoms become exaggerated. Borborygmus is often present, at times an embarrassing audible rumbling. In a thin walled abdomen a visible peristalsis is evident. The stool may consist of hardened masses. There may be red blood present when the tumor is in the sigmoid or rectum. Mucus is present. When the tumor is in the rectum tenesmus is a dominant symptom.

After a period of months or years of partial obstruction the proximal colon becomes greatly distended and hypertrophied, assuming the dimensions of a colon in Hirschsprung's disease. Later the small intestines begin to balloon, and the space reserved for the stomach becomes diminished. Peristalsis continues either iso- or anti- and the situation is serious.

Rankin estimates that acute obstruction exists in 5 per cent of cases and that it sometimes comes without warning due to some complications such as abscess of the bowel wall, perforation of the bowel proximal to the tumor, or peritonitis due to a thinning out of the colon, permitting bacterial transmission.

DIAGNOSIS

The early symptoms of carcinoma of the colon are indefinite and frequently are not severe enough to cause the patient to seek advice. At times a mild abdominal pain comes in attacks which heretofore had not existed and a former regularity of the bowel is lacking, so that the patient's attention is directed to his welfare. The common fault lies in failing to look for a carcinoma when suspicion of its presence should be aroused by the history. Whether the patient is young or old and an ever increasing constipation with crampy pain in the lower abdomen is present, it is indeed wise to consult a physician. If the history of the patient indicates that the change in bowel habit has been over a period of months, then X-ray studies should be made, following the barium head in its progress and controlling the findings by a barium enema.

Fig. 3. Case 3. Drawing of specimen.

A bimanual rectal examination is very simple and should be made. This does not enable one to palpate the right or left limb of the colon, but it will map out a mass in the sigmoid. The urinary bladder should always be empty when making a bimanual pelvic examination, as this will often spare you much perplexity as to the presence of some soft tumor. Dr. John Deaver, at one of the International Assemblies, described in his characteristic manner how he spared a woman an operation by draining the tumor through a catheter in the urethra.

Proctoscopic examinations, in most instances, can now be done in the office with the newer lighted instruments. The patient should be well prepared. A sensitive or tight anus may require a local anesthetic before the proctoscope is inserted, but in the average patient there is no difficulty.

A bimanual examination is next made. Just as a prostate can be outlined from a bimanual examination, by repeatedly coaxing the patient to relax, so one may be able to detect even small masses in the pelvic colon if actual distention does not already exist.

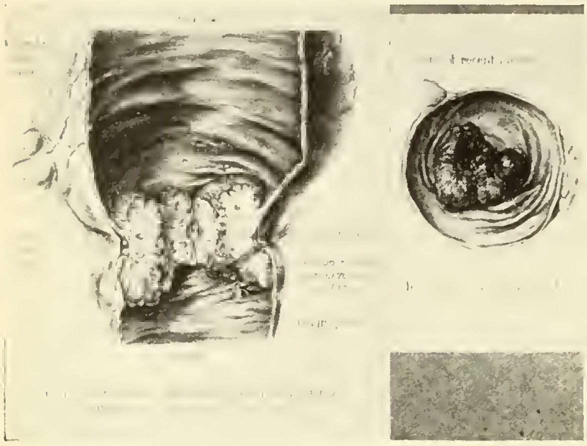

Fig. 4. Case 4. Drawing of tumor from specimen showing complete obstruction.

The barium enema is an invaluable method for determining a filling defect or an obstruction. The enema column is full and dense and can be watched, while in a barium meal we rely upon the goodwill of the colon to propel a full barium column. This does not always take place. It is broken up and widely scattered and gives one in many instances no clue, and no clue is a negative diagnosis. The literature reveals just such situations repeatedly.

The barium enema is without doubt the most valuable diagnostic procedure. In attempting to give a barium meal, we are often confronted by vomiting and anti-peristalsis and our purpose is defeated. Air filling of the colon may help localize a tumor.

In the literature grave warnings are expressed of the consequences of giving a barium meal in obstruction. I have never seen it do any harm.

At the Mayo Clinic a roentgen technic which originated in Schmieden's Clinic in Frankfort, is now used for diagnosing polyposis. This consists of giving a barium enema, then permitting the patient to completely empty the bowel and insufflating the colon with air. A lacy appearance of the colon shows clearly the outline of the polyps.

A barium enema may appear totally blocked at the point of obstruction when the obstruction is not actually complete, the tumor acting like a valve.

Some years ago Moynihan pointed out that irrespective of the site of the obstruction in the colon the cecum distends to a greater degree than any other part.

Just as a glycosuria is not always a diabetes, so also a blood picture of primary anemia is not always due to a pernicious anemia. Rankin says that: "No patient should receive a diagnosis of pernicious anemia until a thorough examination of the entire colon has precluded the possibility of a malignant growth in the right half." Schmieden incidentally found an eosinophilia of 7 per cent in rectal carcinoma and says that several authorities consider eosinophilia characteristic of polyps.

SURGERY

Whether the patient with a carcinoma of the colon or sigmoid is operable must be determined. Kauffmann reports 51 per cent of his cases inoperable. The site of the tumor with its symptoms determines the modus operandi.

In a general way there is a uniformity of thought as to the method of choice, but in some of the important details there is considerable variance. In approaching the surgery of colon carcinoma, I prefer to describe in detail the technic used in advanced cases which may be easily adapted to the earlier ones.

Rankin has simplified the preoperative measures thus: (1) attention to the general condition; (2) reduction of local infection; (3) colostomy; (4) spinal anesthesia.

The patient with carcinoma of the cecum will often have a profound anemia without obstruction, while in a left sided carcinoma a high grade of obstruction may be present. Antiperistalsis, nausea, vomiting, inability to take food or liquid, dehydration and acidosis may result from the obstruction, and hypodermoclysis of one to three quarts of 5 per cent glucose may be required as an emergency measure, taking away all liquids and food by mouth.

An exploratory operation is indicated to determine the extent and site of the tumor and metastases, and to institute relief for obstruction. Fortunately metastases are rarer than in gastric carcinoma.

Should metastases be extensive and the local involvement beyond hopes of removal, then the patient should be spared an unnecessary and ill advised attempt at removal and would live longer with a colostomy. Kauffmann says: "It is useless to operate in the presence of metastases or peritoneal involvement." Polya corroborates this view. Demonstrable involvement of lymph nodes offers a poor prognosis.

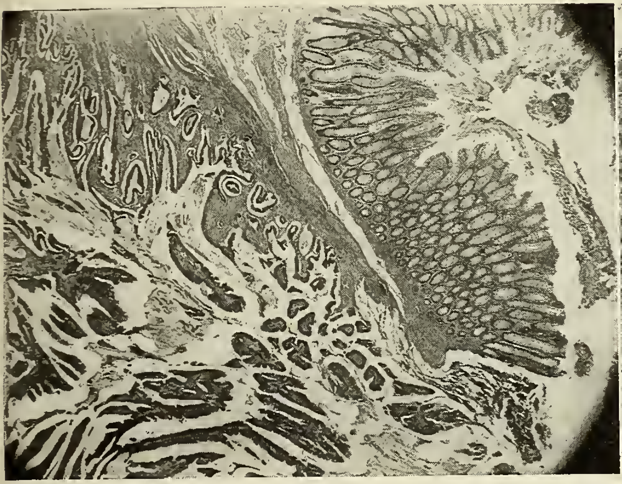

Fig. 5. Case 4. Microscopic section showing sharp borderline between normal and malignant structure.

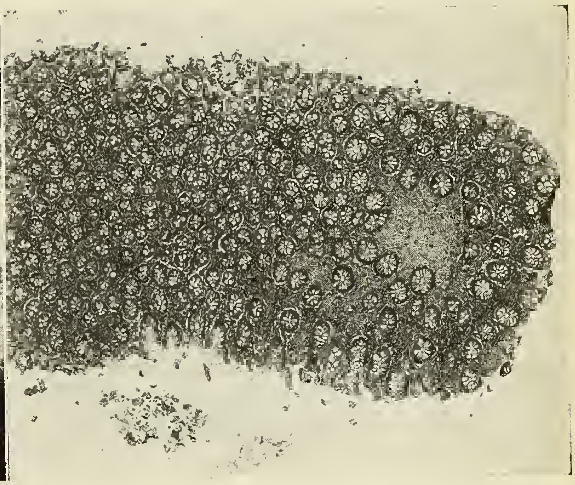

Fig. 6. Case 4. High power magnification of benign polyp.

Primary resection in the presence of ileus is, according to Kauffmann, an operation equal to murder, having a mortality of 80 per cent. Wide resection must be made. Whereas in gastric carcinoma a one inch margin beyond the tumor is rather safe, this does not hold true for the colon.

In a carcinoma of the splenic flexure and descending colon, the left third of the transverse colon, the splenic flexure and the descending colon to the region of the sigmoid junction should be removed. Horsley has advocated this resection. There must be absolutely no tension on the suture line. The ascending or descending colon is readily mobilized by cutting the parietal peritoneum on the outer side. Lifting the colon medianwards, the mesentery is readily presented and enlarged lymph glands can be located. A triangular segment of the mesentery is removed with the segment and the gap carefully sutured. The proximal and distal ends are now sutured end-to-end.

We all agree with Polya that the suture of the large intestine is much more difficult than that of the small bowel because of its blood supply and thin wall. In addition it has annoying fatty appendages and wide mesenteric attachments. Polya uses the appendages to reinforce the suture line. With obstruction, there is always a great difference in the lumen above and below the obstruction.

Polya advocates the open method, cutting the bowel with a knife, sponging the mucus from the open bowel and then suturing. On the right side the end-to-side anastomosis of ileum to transverse colon overcomes the difference in lumens. Polya reports leaving the transverse colon end on the exterior for relief from gas. This method caused an intestinal strangulation in one clinic and was discontinued.

Mikulicz, for twenty years in the Breslau Clinic, advocated his well known exteriorization method. Kauffmann reports that results in primary resection, since Kuettner has been there, have been so successful that in well chosen cases the Mikulicz method is not used.

Bell is of the opinion that the Mikulicz operation should be abandoned, except where gangrene of the bowel exists, owing to the long period of hospitalization, high percentage of recurrence, danger of thrombosis in vessels and postoperative herniation.

Rankin reports in a series of cases a 12 per cent recurrence in the incision with the Mikulicz technic, so he has devised a modification. He applies his two bladed clamp to the proximal and distal segments of the bowel, removes the loop, closes the rent in the mesentery, sutures the peritoneum around the segments, leaving the clamp on forty-eight to sixty hours without disturbance to the patient. No food is given by mouth, but glucose subcutaneously is administered. After sixty hours the proximal blade is opened, gas is permitted to escape, and in a week the clamp falls off the distal end. The spur is cut as in the Mikulicz operation. In one-half of the patients the bowel closes spontaneously. In a closed end-to-end anastomosis the colostomy may be closed in three weeks.

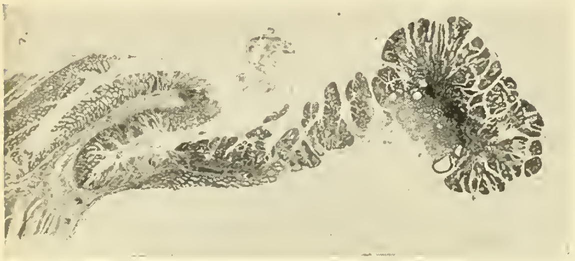

Fig. 7. Case 3. Low power magnification of malignant polyp.

Diet following operation is important and should contain food low in residue and rich in carbohydrate value. Samson Wright, in applied physiology, states: "The feces are not derived to any extent from ingested food, but mainly from the secretions of the alimentary canal. The feces of starving animals do not differ in composition from those of normally fed animals, but are less in amount.

PROGNOSIS

Kauffmann estimates a mortality of 53 per cent in cases of carcinoma of the colon with obstruction, following preliminary operation and resection.

Kauffmann hopefully says that: "Metastases are seldom after three years." Other authors say five years. Turner feels that the mortality has been halved since preliminary operation has been adopted.

Turner and W. J. Mayo advise wide resection even if metastases are present, saying that metastases progress much slower when the primary tumor is out.

Schmieden and Westhues determined that in one instance a recurrence in six months was due to a malignant polyp proximal to a previously excised carcinoma, since metastases do not have a tendency to form an annular constriction.

CASE REPORT

Case 1.—Mr. M., aged 63, was first seen August 22, 1921. The patient complained of a rather sharp pain in the abdomen of a month's duration. His abdomen has not been right for the past four years. His appetite has been good, but he has been very constipated. There has been a loss of ten pounds in the past month. Following severe abdominal cramps he has passed black stools.

All physical findings were negative. A bimanual rectal examination was not possible as the anus was very tight. Following the perianal injection of novocain a bimanual examination was easily made and we could make out a large mass in the left pelvis.

Impression: (1) carcinoma of sigmoid; (2) diverticulitis.

Upon operation under ether on August 31, 1921, a large tumor mass was found in the pelvis. It was freed with difficulty and lifted entirely out of the abdomen. Primary resection seemed so feasible that the mass was removed and an end-to-end anastomosis done. A colostomy of the proximal loop was made. A segment of twelve inches was resected, and there was no tension on the suture line.

Microscopic section showed an adenocarcinoma. On gross section we also found considerable inflammatory involvement and a pus pocket in the wall of the thickened bowel.

The patient bore the operation well and by the twentieth day had natural formed stools.

In June, 1922, optic atrophy made its appearance. The Wassermann test was found to be negative and X-ray therapy was instituted.

In May, 1925, the patient began having intermittent hematuria, occurring for a day every two weeks. There was no pain nor frequency, but blood clots passed. This condition was not reported until May, 1926, when a cystoscopic examination showed an ulcer near the dome of the bladder.

Diagnosis: Carcinoma metastasis.

A series of X-ray treatments was given during May, June and July and in August cystoscopic examinations showed the ulcer to have diminished in size. By December the patient had gained twenty pounds and had noticed hematuria only once since July.

In January, 1931, he was failing rapidly although a barium enema showed no bowel involvement. Since the reading of this paper he became extremely exsanguinated from his hematuria and death ensued.

Case 2.—Mrs. M., aged 73, was first seen July 16, 1926.

The complaint was of quite a severe pain in the left lower quadrant accompanied by rumbling and gurgling noises in the abdomen for the past three months. Constipation had been present for the past two months with absolute obstipation for two days. The appetite had been fair but her health had been failing for the past six months and she had lost some weight. There had been no diarrhea.

Vaginal examination was negative. A barium enema showed obstruction in the mid-portion of the descending colon. A barium meal, forty-eight hours later, showed the head of the column in the mid-portion of the descending colon.

Upon operation under ether on July 20, 1926, a mass was found in the distal end of the descending colon. This was freely movable and could be lifted out. There was not much distention of the intestines present. Resection was made one inch on each side of the mass and an open end-to-end anastomosis made. As there was no tension on the suture line and the anastomosis seemed satisfactory no colostomy was done. One week later some fecal discharge developed at the line of the anastomosis, but soon closed. X-ray therapy was instituted in April, 1927.

In May, 1927, a hard nodule was present at the site of the operation. Opening this resulted in a fecal fistula. A colostomy bag was worn and the patient felt improved.

By July a large abscess had formed near the site of the original incision and the carcinoma had spread all through the incision.

Death occurred on July 6, 1928, from metastases in the liver.

Case 3.—Miss C., aged 35, single, complained of pain in the abdomen, constipation and intestinal cramps. The constipation had been present since January, 1928, but was relieved by mineral oil.

An X-ray laboratory reported the bowel normal. The condition grew progressively worse so that cathartics and enemata failed to act. Examination in our laboratory showed an obstruction in the descending colon. On operation, March 30, 1928, an annular cauliflower mass the size of a walnut attached by a broad base was found completely obstructing the lumen. Microscopic examination showed the presence of an adenocarcinoma.

A segment of the colon near the sigmoid was resected which included about one inch of intestine on each side of the tumor mass. The patient remained entirely without symptoms for two years, when there was a recurrence at the site of the anastomosis larger than the primary tumor and obstructive in character. The patient, a very intelligent young woman, declared in no uncertain terms that the colicky pain and disturbed bowel habit were again identical with the symptoms she had had before, which in the interim had all disappeared.

An extensive resection following a cecostomy was carried out in October, 1930. We found a recurrence with two distinct tumors, one a large cauliflower mass with a small base which on section exhibited the coniferous tree-like design with its individual pedicle (Fig. 3). Healthy mucosa existed on each side of each tumor. This appears clearly in the drawing. It was of great interest to me that we found proximately a polyp with a pedicle 2.5 cm. long on a healthy base (Fig. 7). This was pronounced by Dr. E. T. Bell as near-malignant and belonging in group three of Schmieden and Westhues.

Case 4.—Mr. C., aged 33, was first seen July 20, 1930. His complaint consisted of hiccoughing, pain in the epigastrium, a general soreness of the abdomen, and recent constipation. For the past three days he has had a severe crampy pain in the left abdomen with obstipation, hiccough, nausea and vomiting of green and brownish material. For two years he had suffered from an increasing constipation, without attacks of diarrhea. For three months there had been a gurgling and rumbling in the bowels. The abdomen was rounded, but did not give the impression of any marked distention. No red blood was noticed in the stool. In the hospital the hiccough persisted.

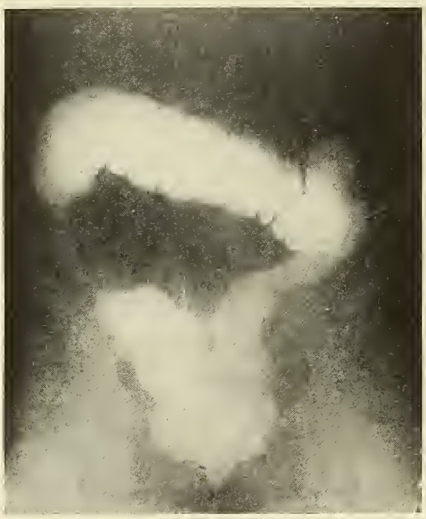

Fig. 8. Case 3. Barium enema after resection of left third of transverse colon and all of descending colon. Ascending colon shows spasm of colostomy due to closure ten days before.

The patient was in much distress from the hiccough and frequent vomiting, sometimes of dark blood. Glucose had to be administered intravenously to counteract acidosis.

In this particular instance his symptoms all pointed to a gastric lesion and our attempt was to visualize the stomach. To add to our confusion the stomach was deformed and situated extremely high. An irregular filling defect could not be interpreted. The esophagus was filled and remained filled for six hours. The first ray of light came when the jejunum appeared to be severely distended and ileum, cecum, ascending colon and transverse colon were found successively to be displaced and greatly ballooned. The transverse colon was situated anterior to the stomach. The head of the barium column finally halted in the upper part of the descending colon (Fig. 2). To verify our findings the barium enema head came to rest within a half inch of the meal head. A dense shadow three-fourths of an inch in diameter in the upper left abdominal quadrant was freely movable (Fig. 1). In the lower right quadrant there was a group of dense shadows, nine in all. The first radiograms revealed a severe jejunal distention, and later radiograms showed also distention of the ileum and colon to a high degree. After twenty-four hours the stomach rugæ still retained barium and the head of the meal was in the descending colon.

For two years the patient had sought medical advice and was graciously recommended to take another laxative each time he came for relief of his symptoms. No

X-ray examination had been done. I believe we are justified in recommending X-ray examinations, not only in such advanced cases, but on suspicion of trouble.

Diagnosis: Carcinoma high in the descending colon.

A preliminary cecostomy was performed on July 26, 1930, under spinocain. A mass was found in the descending colon (Fig. 4).

On August 8, under spinocain, resection of the left third of the transverse colon, the splenic flexure and the descending colon was made to near the sigmoid. The left colic artery and the glands were resected with the mesentery. A number of enlarged lymph glands were encountered, one at the apex of the mesenteric triangle to be removed at the junction of the left colic artery with the mesentery. This gland was removed individually and later proved to be malignant. The liver was free and no other metastases were seen or felt. An open end-to-end anastomosis was made. The dense shadows proved to be hard enteroliths.

I believe every lymph gland in the left mesentery was involved (Fig. 1). There were about six glands the size of a pea and the most proximal at the apex of the triangle of mesentery was completely involved with colloid cancer.

In the gross specimen the tumor was an annular type completely obstructing, and about 3 cm. distally from the tumor was a small polyp 1 cm. high on a healthy base which on section was benign (Fig. 6).

Convalescence was stormy for a time due to severe griping abdominal pain. The intestinal suture line held well and his stomach and bowel function became normal.

The cecostomy was closed on August 29, and, aside from some griping, convalescence was uneventful and the patient went to work as engineer on October 15. By November he weighed 156 pounds, having gained 17 pounds in two months.

ACUTE MECHANICAL OBSTRUCTION OF THE LOWER BOWEL*

James A. Johnson, M.D.
Minneapolis

Much confusion has arisen in the past from a too general consideration of intestinal obstruction, without regard to the importance of its location. The symptoms, treatment and prognosis may vary greatly in relation to the type and location of the obstruction. I shall consider here only the mechanical variety, located in the lower ileum and colon. For purposes of analysis the types will be classified as: (1) simple, (2) strangulated, (3) complete, and (4) incomplete.

In simple obstruction there is no material interference with the blood supply. It most often occurs high in the canal, as in obstruction to the pyloris or duodenem by carcinoma, congenital bands or cicatricial contractions. It may also be found in the lower bowel, but if allowed to progress in this location, will nearly always cause interference with the circulation and go on to strangulation. The cases of simple obstruction occurring in the lower bowel are usually the result of growths and foreign bodies, such as gallstones. If the block is complete, strangulation may occur early because of extensive bowel distention.

In obstruction with strangulation there is a definite interference with circulation. Such cases usually result from bands, hernia, or intussusception, where there is a more or less complete blocking of the circulation early in the obstruction. As a rule in obstruction with strangulation the condition is more serious, and the mortality is much higher than in cases of simple obstruction.

The complete and incomplete types of obstruction are self-explanatory. Some are complete at their onset, but many begin as incomplete and later become complete. It is obvious that the more complete an obstruction is, the more serious is its outlook.

The location of the obstruction is an important factor. In the upper bowel obstruction the toxemia is not so great as in the lower. The chief difficulty in this type lies in the fact that the patient begins to vomit early, and therefore rapidly becomes dehydrated, and loses his chlorides. If the condition is not recognized early, dehydration, hypochloremia and starvation may cause a rapid termination. Today, however, because of the almost universal understanding and application of the principles of blood chemistry, these cases do not present so serious a problem. The proper administration of water, sodium chloride and glucose will control the danger factors for a long period of time.

In lower bowel obstruction, in addition to the above factors of dehydration, hypochloremia and starvation, there is the added dread of strangulation, toxemia and peritonitis. An obstruction in this location is often insidious in its onset and grave symptoms may not appear until toxemia and even peritonitis are well advanced. For these reasons the mortality is extremely high and the condition should be considered as a separate entity.

With these points in mind, the author has made an analysis of thirty-six consecutive cases of lower bowel obstruction occurring in his private practice during the nine years from January, 1921, to January, 1930. The cases chosen were from private practice, and they received daily, personal observation.

In Table I the cases have been tabulated as to cause, type of obstruction, type of operation and result. Only the cases in which there was a marked interference with circulation were classified as strangulated. In the cases due to inflammatory adhesions, only one was recorded as strangulated. Some of the others may have been, but since only an enterostomy was done, no accurate observations could be made. Thirty-one of the obstructions occurred in the lower ileum and five in the colon.

Table II is a summary of Table I, showing a mortality of 11 cases out of the 36, or 30.55 per cent. A detailed analysis of the mortality is given in Table VI.

It is a well known fact that previous opera-

tions play an important part in the development of acute mechanical obstruction. This is illustrated in Table III. Of the 36 cases tabulated, 20 (55.5 per cent) were the direct result of previous operations on the pelvic organs or the lower bowel.

Table IV shows the number of hours or days that symptoms of obstruction were present before operation. It is impossible to state in a particular case just when an obstruction becomes complete. Some of the cases were undoubtedly incomplete at the onset. Three could definitely be recognized as of gradual onset and were incomplete for a considerable period of time. One was gradual and incomplete. The number of cases is too small to draw any definite conclusion as to the relation between duration of symptoms and mortality; but it is a recognized fact that the longer the duration, the higher the mortality. The above tabulation verifies this statement.

Enterostomy is now considered one of the most important life saving measures in advanced cases of bowel obstruction. A separate analysis has therefore been made of those cases in which enterostomy was performed, giving duration and type of obstruction, together with the condition of the patient and results obtained. It will be noted by studying Table V that all the cases were advanced and the condition serious. Many of these patients would undoubtedly have died had not enterostomy been done. Of the fifteen patients operated upon, only three died (20 per cent); two from general peritonitis and one from lobar pneumonia.

Chronic salpingitis	1
Sigmoidostomy	1
Carcinoma of the colon	1
Enterostomy	1
TOTAL	20

(Of these, seven cases occurred during post-operative convalescence.)

Of the cases in this series which resulted in death, two were due to general peritonitis which was present at operation, one being of three and the other of four days' duration. One patient died from peritonitis or toxemia. This was an out-of-town patient, and could not be observed; but if an enterostomy had been done and proper postoperative care given, the patient would probably have lived. One died from peritonitis, and had a complete paralytic ileus. Only an enterostomy was done. One died from toxemia and operative shock, the obstruction being of four days' duration, and the patient almost pulseless when first seen. Operation was no doubt a useless procedure.

One patient had a paralytic ileus for five days. He had a severe asthma and myocarditis. No operation was done. Postmortem examination showed that a band had obstructed the descending colon. The obstruction was complete, but there was no damage to the bowel or signs of peritonitis. Postmortem examination of the chest was not permitted, but the death was clinically a cardiac one. An early enterostomy would probably have prevented this patient's death.

In one patient with a long-standing myocarditis, an incomplete obstruction was relieved, and gas and stool were freely passed. Death occurred four days after operation, and was due to cardiac failure.

Another patient was relieved of the obstruction; the enterostomy tube drained freely and the distended abdomen returned to normal; but he died three days after his operation from extensive lobar pneumonia, as proved by postmortem examination.

Three patients died from shock following operation. Two of these were eight and nine months old respectively, and had an intussusception of the ileum into ileum, with complete gangrene. Resection and anastomosis were done. One died twenty-four hours and the other three hours after operation. The third patient, a child three days old, had complete congenital atresia of the colon and lower ileum. Resection was done, but the child died twenty-four hours later.

MORTALITY

In 1925 Tuttle[1] compiled a list of the mortality rates given by various observers. These were as follows: J. M. T. Finney, 36 per cent; C. T. Horine, 40 per cent; C. L. Scudder, 60.4 per cent; St. Thomas Hospital, London, 58 per cent; E. P. Richardson, 41.5 per cent; Guillaume, 63.2 per cent; Deaver and Ross, 42 per cent; C. L. Gibson, 43.2 per cent. The mortality rate in Tuttle's own group of cases was 50 per cent. Holden,[2] in a survey of 135 cases of all types in 1926, gave a mortality rate of 19.2 per cent.

In my series of cases I found the mortality rate to be 30.55 per cent. Of the patients who died, eight died as a direct result of the obstruction (22.2 per cent), two from heart complications (who would otherwise no doubt have lived), one from lobar pneumonia. Ten were completely obstructed, one incompletely (pneumonia death), seven were strangulated, one was no doubt strangulated, but since only an enterostomy was done no accurate information could be obtained; one, not strangulated, had a cardiac

death, and one had congenital atresia of the bowel and died from shock. With the exception of the last case mentioned, all of the patients that died as a direct result of the obstruction (22.2 per cent) were strangulated.

The death rate from this condition depends largely upon the type of the obstruction and its duration. The rate is high in cases with strangulation. The greater the area of strangulation, the more serious the outlook will be. In this type early operation is of great importance. Delay is no doubt the greatest single factor to account for so high a mortality. It is probably safe to assume that if operation could be undertaken before profound toxemia and peritonitis develop, the mortality rate could be brought below 10 per cent.

CAUSES OF DEATH

Much has been written and many opinions expressed as to the cause of death in acute bowel obstruction. The usual expression is, "The patient died from toxemia." There is no doubt that the term "toxemia" has been used to include a multiplicity of causes which to many of us have not been entirely clear.

The various causes of death can be grouped into three classes: (1) changes in blood chemistry; (2) strangulation and shock; (3) toxemia and peritonitis.

The changes in blood chemistry are: (1) dehydration and loss of sodium chloride, due to vomiting, resulting in acidosis or alkalosis; (2) starvation from lack of food intake; (3) an increase in urea and non-protein nitrogen from toxic absorption and lack of elimination. In all probability some deaths in the past could be traced directly or indirectly to these causes. (McIver and Gamble[3] by experimental data have reached the same conclusion.) None of these changes is rapid, except in high obstruction, and with the proper administration of water, sodium chloride and glucose should not occur in a sufficient degree to cause death.

Clinically, it has long been recognized that when a large section of bowel is suddenly and completely strangulated, a rapid severe shock often follows. This has been proven experimentally by Foster and Hausler,[4] who even claim shock as a primary cause of death. Severe shock from strangulation is well illustrated in two of the above cases in which sudden extensive complete strangulation took place from intussusception of a large section of ileum into ileum. There was only slight dilatation of the bowel and no sign of toxemia or peritonitis, yet there was profound prostration and both patients died shortly after the operations from the added shock. Shock phenomenon following sudden interference with circulation is not confined to lesions of the intestinal tract. It is well exemplified in cysts with twisted pedicles and emboli blocking mesentery, lungs and extremities.

Toxemia and peritonitis are the causes of death in practically all cases of lower bowel obstruction. Let us consider what happens when the bowel is mechanically blocked. First, peristalsis is increased in an effort to relieve the obstruction. Bowel contents and gas cannot pass and dilatation takes place. As this continues, dilatation becomes more marked and there is a constantly growing accumulation from ingested fluid and intestinal secretions, all of which, in its stagnant condition, becomes a good culture medium for anaërobic intestinal bacteria. As accumulation continues, dilatation progresses, so that peristalsis becomes weaker. There is interference with circulation, the bowel looks cyanotic and dark spots appear, due to rupture of muscle fibers and smaller vessels or areas of thrombosis. During this stage considerable free fluid appears in the abdomen. Peristalsis grows weaker and finally disappears. The bowel is covered with gangrenous areas and leakage of the toxic contents takes place, general peritonitis develops, and we have the terminal stage of bowel obstruction.

The absorption of the toxic contents of the bowel has long been considered the cause of death. Many investigators have attempted to isolate a toxin or an organism responsible for this. Bower and Clark[5] state that of the few anaërobes found in the intestine, the *Bacillus welchii* is the only one that produces a toxin. In an obstructed bowel it multiplies rapidly and is supposed to account for a large amount of the gas distention. It causes a profound toxemia, much resembling that of gas gangrene. Bower and Clark treated twenty-five cases with an antitoxin from the *Bacillus welchii,* and believe they noticed much clinical improvement from its use. However, McIver and White's experimental observations[6] showed large numbers of the *Bacillus welchii* in the obstructed loops, but they could not ascribe toxemia to their presence. Foster and Hausler[4] strained the content of an obstructed bowel through gauze, and injected it intraperitoneally into dogs. The dogs became quite sick, but none died. Wangensteen and Chunn[7] injected filtrates from the contents of obstructed bowel and from normal bowel intraperitoneally into dogs, and proved that all intestinal filtrates are toxic; but they are not any more toxic from the obstructed than from the normal contents.

My clinical observations have been that an obstruction, if simple and without any strangulation, may be present for several days without much evidence of toxemia. The bowel may be very much distended, and contain large quantities of toxic fluid, yet the patient's general condition may be good. If the obstruction, however, progresses to strangulation, the picture is quite different; there is general prostration, the pulse grows weak, there is cold perspiration and cyanosis and the patient is profoundly ill. The general condition of the patient seems to depend upon the extent of the strangulation, and not on the amount of toxic material in the bowel. In some instances, strangulation can be so gradual that it does not produce the above symptoms. This is well illustrated in one of the cases cited. A patient with a carcinoma of the descending colon had symptoms of obstruction for a month, and had been completely obstructed for five days, yet he walked into the office and did not seem very sick. He was operated upon within a few hours. The colon and ileum were tremendously dilated and covered with necrotic areas through which the bowel contents were leaking into the abdomen. He had purulent peritonitis.

It is the acute strangulated case which presents the early profound toxemia. The more extensive the strangulation and the more quickly it develops, the more profound the toxemia will be. It is quite probable that we often confuse the prostration resulting from an extensive progressive strangulation with the toxemia which we suppose results from accumulations in the bowel. As strangulation progresses, so does toxemia. It is, therefore, quite reasonable to assume that the toxemia we often speak of as due to absorption of toxic material from the bowel contents is in reality due to the toxicity which arises from a progressing strangulation. As strangulation progresses, peritonitis develops, and gives us the final picture of death.

SYMPTOMS AND DIAGNOSIS

Pain is invariably the first symptom. It is intermittent and of a colicky nature, with intervals of rest. It is due to peristalsis attempting to force the bowel contents past the obstruction. As the bowel becomes over-distended and loses its contractibility, pain becomes continuous.

Shock is often marked at first in the acute mechanical type, especially when strangulation occurs early, as in intussusception. The primary shock may disappear, but will reappear as strangulation progresses.

Vomiting may occur early when obstruction is sudden and complete. It is usually a late symptom in lower bowel obstruction, and depends on the amount of fluid ingested. In most cases it does not occur until the bowel is over-distended and reverse peristalsis sets in. It is then an overflow, regurgitating type.

Abdominal distention is earliest and most pronounced in the loose, flabby abdomen. It is less evident and often misleading in the young muscular individual. It is difficult to estimate in the obese. In high obstruction, it is usually absent.

Fever and leukocytosis are absent in all non-inflammatory types at first, but appear as leakage takes place and peritonitis develops.

Obstipation is often misleading in obstructions above the colon. The first two enemas may bring good results of gas and stool from the colon below the block. This tends to confuse diagnosis and leads to delay if not properly evaluated.

The stethoscope has been a valuable aid in diagnosis. The peristaltic waves forcing gas and contents onward produce quite a characteristic sound. The gas as it passes on through the loops produces a gurgling sound, and when it meets the obstruction there is often quite a commotion. Either it passes through the obstruction with a rush, or is forced back up the bowel with a piping, blowing sound. The site of the obstruction can often be located in this way. The fluid passing through the loops produces a tinkling, metallic sound quite characteristic of obstruction.

The X-ray has great practical value in diagnosis. This has been recognized for a long time, but has not had general application. Normally, there is not enough gas in the small bowel to be recognized with the X-ray. In obstructions in the ileum, collections of gas can often be seen quite early. Later, as the bowel becomes distended, it assumes a horizontal position in the abdomen and the gas shadows have a "step ladder" arrangement, as described and illustrated by Case.[8]

In obstruction of the colon, large gas collections can often be seen in the proximal loop, stopping abruptly at the block. If a colon obstruction is suspected, a barium enema should be given to prove and locate it. This is especially valuable in elderly people who have had no previous operations, since it is likely to be due to malignancy, and its location is valuable to the surgeon in planning his operative procedure.

Blood chemistry changes in low bowel obstruction as a rule are found only in late, neglected cases. This is quite the reverse in high obstruction, where dehydration and hypochloremia appear early. Chemical changes must always be sought and proper tests made in order to correct any pathologic change.

TREATMENT

There has always been, and still is, an urgent need for early diagnosis and prompt surgical intervention. This cannot be over-emphasized. There is usually too much speculation concerning the possibility of an incomplete obstruction correcting itself. Cathartics and morphine are responsible for a great deal of delay and damage.

Preoperative considerations. The majority of patients are unfortunately in poor condition when first seen by a surgeon. There is often considerable dehydration and toxemia. The immediate consideration is, therefore, the administration of proper quantities of water, sodium chloride and glucose. This will not only correct dehydration and blood chemical changes, but will also tend to overcome toxemia and promote elimination. This need not consume any additional time. It can be done while the patient is being prepared for operation.

The operation. The choice of operative procedure will depend on the condition of the patient. In a profoundly sick case in which there is little or no evidence of peristalsis, it is usually unwise to consider a laparotomy. A jejunostomy in such instances is the operation of choice. This can be done in the patient's room under local anesthesia.

In patients who are in fair condtion, laparotomy should be undertaken. It is quite probable that spinal anesthesia, carefully guarded, will be the choice in the future. When the abdomen is first opened, look for a collapsed bowel, and carefully locate the point of obstruction. Do not permit evisceration. It is not necessary, and causes shock. If the bowel is greatly distended, enterostomy should be done, preferably just above the obstruction. Drain the bowel at once if conditions permit. This is especially necessary in advanced cases, as it allows the bowel to regain its peristalsis. If distention and strangulation are so great that peristalsis is absent, an enterostomy will do no good until the bowel is emptied of its contents. By relieving the bowel of its contents, the circulation will return, and the bowel will contract and regain its peristalsis. It is not so much the removal of the toxic contents that benefits the patient as the fact that the distention and strangulation are relieved.

In advanced cases where resection of the bowel is necessary, it is often advisable to do a two-stage operation, the bowel being drained first and later resection and anastomosis done.

Postoperative care consists in supportive measures by the administration, subcutaneously or intravenously, of sufficient quantities of water, sodium chloride and glucose to correct or prevent dehydration, starvation or pathologic blood chemical changes. If there is vomiting or gastric accumulations, these should be relieved by gastric lavage. If the bowel remains distended and does not respond to enemas and pituitrin, a hypertonic salt solution should be given intravenously. In some cases spinal anesthesia, as described by Studdiford[9] and others, has given good results.

CONCLUSIONS

1. In a clinical study of acute mechanical intestinal obstruction, careful consideration should be given to type and location.

2. Strangulation is the most serious complication in low bowel obstruction and occurs in nearly all advanced cases.

3. Toxemia from strangulation and peritonitis is the greatest single factor as a cause of death in low bowel obstruction. The toxemia is probably not due to bacterial toxins in the bowel, since it does not occur without strangulation. The progressive toxemia is no doubt due to strangulation or peritonitis, or a combination of both. The amount of toxemia is in proportion to the extent and rapidity of the strangulation.

4. Enterostomy, especially in advanced cases,

is a great life saving procedure. Its function is not to drain toxins from the bowel, but to relieve distention, thus improving circulation and allowing the bowel to contract and regain its peristalsis.

5. Delay in diagnosis and surgical intervention is responsible for the high mortality in intestinal obstruction. Watchful waiting, morphine and cathartics should be replaced by prompt surgery. In this manner the mortality could be reduced to below ten per cent.

THE MILO BAR BELL

Those who study the fantastic advertisements of the "big muscle boys," appearing in such magazines as *Physical Culture,* will remember the pictures of the superman, with the musculature of an ox, holding aloft a particular brand of dumbbells known as the "Milo Bar Bell." From the advertising, one gathers that by the use of this particular device the puniest and weediest of individuals can develop into veritable Samsons. It appears that the Milo Bar Bell Company, which exploits this device, is a trade name used by one D. G. Redmond. The Federal Trade Commission has issued an order to Redmond to cease and desist from "representing by pictures, statements or otherwise, that physical development reasonably attributable to natural growth has been brought about by the use of respondent's bar bell or other appliance or course of instruction." (Jour. A. M. A., May 2, 1931, p. 1527.)

SOLVOCHIN NOT ACCEPTABLE FOR N.N.R.

Solvochin (Spicer & Co., Glendale, Calif., distributor) is a solution of quinine hydrochloride containing small amounts of quinine base together with sufficient phenyldimethylpyrazolon (antipyrine) to render the basic quinine soluble. It is claimed that the solution possesses advantage over the usual quinine preparations in that it may be injected without local irritation. It is recommended in the advertising as the medicament of choice in the treatment of lobar pneumonia, and it is claimed to be essential that the injections of quinine for the treatment of this disease be by the intramuscular route. The Council on Pharmacy and Chemistry declared Solvochin unacceptable for New and Non-official Remedies because it is marketed with unwarranted therapeutic claims. (Jour. A. M. A., May 2, 1931, p. 1477.)

ACUTE ABDOMEN*

Ralph T. Knight, B.A., M.D., F.A.C.S.
Assistant Professor of Surgery, University of Minnesota
Minneapolis

THE term "acute abdomen" is used to signify the sudden onset of a severe pathological condition in the abdomen, or the climax of a more chronic process. It is announced by pain, this being the outstanding complaint of the victim. It is frequently accompanied by nausea and vomiting, and, with more variance, by the other symptoms and signs.

The acute abdomen is a favorite literary subject. However, it is so demanding, so critical, it so taxes one's ability and judgment, its mortality is so high, that we should crystallize our thoughts so that they will work to the best advantage when we are confronted with the emergency.

Most writers list all of the acute intra-abdominal diseases and give in order their symptoms, signs and differentations. It seems to me helpful to think first of the possible pathological processes and their symptoms and signs, and then to attach the diagnosis to the organ which we may determine to be involved.

Hertzler[3] divided all acute abdominal lesions into two classes: (1) perforative; (2) thrombotic or strangulative.

It makes the situation still more clear to divide them into the following classes: (1) obstruction; (2) strangulation or thrombosis; (3) local inflammation; (4) peritonitis. These may exist singly or in combination, or in progression, one after another. According to their severity and the organs involved, they present the symptoms and signs of the acute abdomen in varying degrees.

I. Simple obstruction may come on gradually or suddenly:
   a. Gradually, due to the growth of a mass, narrowing of a stricture, development of adhesions, or gradual change in position of a foreign body.
   b. Suddenly, due to a foreign body or a kink. The more suddenly it occurs, the more sudden and severe are the symptoms.

Pain is the outstanding symptom. Its character is intermittent or colicky. Its location is over the point of obstruction, radiating according to the organ affected.

For the gall bladder and biliary ducts it is under the right costal margin, referred to the right scapular region.

For the kidney and ureter it is in the lumbar or lateral abdominal region referred downward through the iliac region to the bladder, vulva, testis or penis.

For the appendix it is in the right iliac region, or in the epigastrium, gradually becoming localized over the appendix.

For the bowel it is in the region of the obstruction.

A sudden, complete obstruction produces the most severe pain and is usually accompanied by vomiting. Frequently there are mild signs of temporary shock. After the shock the patient tends to double-up, roll about or walk the floor with each recurring spasm of pain. There is some tenderness over the obstruction if it causes distention of the organ obstructed.

As gas, fluid or material collects behind the obstruction, the organ distends and the pain becomes more continuous or the remission less complete.

Distention of the gallbladder, stomach and intestines may be made out by inspection, palpation and percussion.

Early differentiation between intestinal obstruction and ordinary gas colic taxes our skill. A metallic tinkle heard on ausculation during a spasm of pain, as the intestional contents strike the obstruction in a distended loop, is considered by Wangensteen[6] and others to be one of the most helpful signs. It is not always true to form and one must be familiar with intestinal sounds to recognize it. Some time ago, I saw a patient with a strangulated hernia at frequent intervals during the first twenty-four hours while trying to crowd the stubborn patient into the hospital and heard no tinkle. At operation the obstruction was complete and the incarcerated ileum quite dark. The next day another patient, who was vomiting, presented what I thought was a perfect periodic tinkle and increasing distention. An immediate flat film showed no obstructive gas distribution and the symptoms subsided the next day.

---

*Read before the Medical Staff of the Abbott Hospital, Minneapolis, January 6, 1931.

The X-ray method, or so-called scout film, should always be used as soon as obstruction is at all suspected as it gives the most reliable help obtainable. Wangensteen states that roentgenologically demonstrated gas in the small bowel is pathognomic. As time goes on, the bowel becomes more and more distended, quiescent and silent, the patient becomes more and more toxic, the vomiting fecal in character. The diagnosis can then be easily made but the mortality is tremendous.

Concerning the appendix, Lockwood[4] lays stress on the fact that all appendicitis starts as an appendiceal obstruction, or, as he calls it, "acute intestinal obstruction involving the appendix," and should be recognized in that stage and operated at that time in order to lower the present high mortality of appendicitis. We agree that this obstruction should be operated upon early, and not looked upon as a medical condition, "just appendiceal colic," as it has sometimes been in the past. However, appendicitis undoubtedly sometimes starts as a strangulation or thrombosis, not always as a simple obstruction.

A tubal pregnancy becomes an acute obstruction of that organ, which, however, develops gradually until it distends the tube and so causes a constant rather than intermittent pain.

II. Strangulation often causes or accompanies obstruction of a hollow viscus. It may come suddenly with extremely severe pain or the twist may slowly close down on the blood supply. There is more shock than with simple obstruction. The pain is more constant but has severe exacerbations as the viscus tries to free itself. If the structure strangulated has no musculature such as the omentum, the ovary or a pedunculated fibroid, the severe exacerbations do not occur unless a nearby muscular organ becomes stimulated, or involved.

Thrombosis or hemorrhage into such organs as the pancreas, omentum, mesentery, ovary, or a fibroid, causes much the same symptoms as strangulation, by shutting off a section of the blood supply and producing swelling and pressure. When this occurs in the pancreas an especially acute picture is produced. It is either preceded or accompanied by the activation of pancreatic enzymes. This produces violent irritation with early necrosis and early and rapid peritonitis. Strangulation or thrombosis of a non-muscular organ, therefore, produces as sudden and dramatic an onset as an acute obstruction, but the ensuing symptoms and signs are of an acute inflammation.

III. Local inflammation, the third lesion to be discussed, may occur as a primary entity, starting at any point in any organ in the abdomen, or it may be a sequel to obstruction or strangulation. In inflammation, also, pain is the first symptom. The pain of local inflammation usually comes on more gradually than in obstruction. Those who are awakened in the night, or suddenly struck during the day, with acute cholecystitis or appendicitis or pancreatitis have an initial obstruction or thrombosis. With the pain of inflammation, strangulation or thrombosis the patient does not toss about as he does with obstruction, but lies quietly in whatever position puts the least pressure upon the inflamed or thrombosed area. The pain is steady and increasing.

Nausea and vomiting usually follow pain, but do not become feculent as in bowel obstruction.

In addition to pain, the great sign indicating inflammation is tenderness. Tenderness is pain caused by pressure. Manual palpation, skilfully applied, with both superficial and deep pressure, first to areas thought not to be painful and then approaching the suspected area by comparison, is the tried and true method of eliciting tenderness. There are other devices especially suited for confirming tenderness in certain organs, notably the appendix.

1. McBurney's sign is tenderness to pressure over McBurney's point.

2. Meltzer's sign. With the examiner's finger pressed deeply over the site of the appendix, the patient flexes the hip on the body with the knee extended. This renders the psoas rigid and causes more pressure against the appendix between the psoas and the fingers, causing pain.

3. Muscular spasm or resistance on pressure over the appendix.

4. Deep inspiration causes pain in the inflamed gallbladder or appendix by pressure from above and motion.

5. The gravity sign. When turned upon the right side pain is caused in the inflamed gallbladder or appendix because of the pressure of the organs upon them.

6. Murphy's sign. Much like the gravity sign in principle, pressure upon the left side of the abdomen causes pain in the region of an inflamed appendix or gallbladder by transmission of the pressure.

7. Rectal tenderness sign. Finger pressure upward through the rectum to the right causes pain in an inflamed appendix, especially if opposed by abdominal pressure. This is especially valuable in children, as in them the appendix region is in closer proximity.

8. The flexed knee sign. The patient tends to keep the knee and hip flexed with the leg supported to lessen pressure on an inflamed appendix which may be compressed between taut psoas and abdominal muscles.

9. Bastedo's test is especially devised for eliciting tenderness in a subacute or chronic appendicitis, and helps differentiate from a stone in the ureter and salpingitis. The colon is distended with air from a Politzer bag until, as shown by percussion, air distends the cecum. Nausea and pain then indicate tenderness or sensitiveness in the appendix.

10. Rovsing's test is the same, except that the cecum is distended with fluid and gas by progressive retrograde pressure from the sigmoid along the course of the colon, preferably with the patient standing.

11. Blumberg's sign, or rebound tenderness, is pain caused by the sudden release of slowly applied pressure, and indicates peritoneal irritation or early localized peritonitis.

All of these signs were collected and beautifully described in a paper by Cranmer[2] in 1925.

Early pneumonia and pleurisy often cause pain and tenderness in the abdomen in the area supplied from the same spinal segment which supplies the pulmonary area involved. This tenderness, however, is superficial, lessening instead of increasing as the pressure is deepened.

With tenderness there is muscular resistance to palpation in proportion to the degree of inflammatory pressure within. This is an elastic resistance and may be partly overcome by gentle firm palpation and voluntary relaxation by the patient, in contrast to the board-like rigidity of peritonitis.

Next to pain, tenderness and resistance, fever and leukocytosis indicate inflammation. These usually rise much higher in pneumonia, pleurisy, and general enteritis than in any local abdominal inflammation, and local inflammation of a serious degree may exist without them, especially if it is the sequel to obstruction or strangulation rather than a primary severe infection.

Tenderness, then, remains the preëminent and outstanding sign in local inflammation.

Acute enteritis and colitis present inflammation with atypical symptoms. The inflammatory products are not confined but have free drainage through the bowel. The pain, therefore, is not steady, but colicky, as it is in obstruction, because of stimulated peristalsis. Contrary to obstruction, however, the peristalsis is productive of diarrhea, the liquid stools sometimes containing mucus and even blood. When this occurs it must be distinguished from the strangulation of intussusception in which a tender mass can usually be felt by either abdominal or rectal palpation.

With enteritis and colitis there is tenderness and moderate muscular resistance over the entire abdomen. Ausculation gives the sounds of very active peristalsis with rapid movement of fluid and gas but without the striking metallic tinkle heard with obstruction. One should take every opportunity to auscultate normal and abnormal abdomens to become familiar with the sounds.

A difficult pitfall which one must always keep in mind is the fact that not uncommonly an acute cholecystitis, appendicitis or diverticulitis develops on top of a typical general enterocolitis.

IV. Peritonitis is usually secondary to local inflammation or perforation of a viscus. It may be a sequel to one of the other three lesions we have been discussing—obstruction, strangulation or thrombosis, or acute local inflammation—or it may itself usher in the acute picture as the result of the perforation of an ulcer.

Peritonitis passes through three stages: (1) primary contamination; (2) reaction; (3) late peritonitis with paralytic ileus.

The typical first stage caused by perforation of a viscus without much warning is ushered in by acute pain and shock with a rapid weak pulse, low temperature and cold perspiration. Respiration is restricted, the abdomen is scaphoid, and there is extreme tenderness and board-like rigidity. The patient lies absolutely quiet, as movement causes great pain. In pelvic peritonitis, as from a perforated sigmoidal ulcer, the rigidity and tenderness are hidden and must be found by deep pressure over the pelvic brim and by rectal or vaginal examination. It must be remembered that there is an inferior abdominal wall as well as anterior, lateral, and posterior.

If the contaminating substance is emitted from a hollow viscus by gushes with recurring peristaltic waves, the pain is accentuated in savage spasms.

The second stage, or reaction, exhibits less pain, a better general appearance, and a normal temperature and pulse, but there is great pain upon movement, and tenderness and rigidity remain. Free fluid may be found and gas may overlie the liver as found by percussion and X-ray.

The third stage ensues shortly. There is paralytic ileus. Vomiting usually recommences, and is without force. The abdomen is distended and tender with lessened rigidity and without visible or audible peristalsis, the face is worried and anxious, the pulse is rapid and small, the temperature variable, the breathing rapid and labored, the blood pressure falls, and death may soon follow.

When acute peritonitis follows the rupture of an acute local inflammation which was under painful pressure, there is at first a relative decrease of pain on account of the released pressure and the first stage is less dramatic, but there is still some shock if the area is not well walled in. If enough adhesions have been built there is no first stage shock and the tenderness and rigidity are restricted to the area involved but are definitely present. When peritonitis occurs by slow extension of inflammation, the earliest sign is rebound tenderness, pain caused by sudden release of slowly applied pressure.

If the contaminating substance is blood, as from the spleen, liver, mesentery, omentum, or fallopian tube, the irritation of the peritoneum is less severe, there is less pain, tenderness and rigidity, varying in proportion to the amount of blood and the rapidity with which it flows into the peritoneal cavity. Shock varies with the amount of trauma to the viscus and the amount and suddenness of blood emission. There is less recovery in the second stage, as blood loss is the main factor.

Rigidity is the outstanding sign of peritonitis. This term is sometimes used too loosely, to indicate the more elastic and more controllable muscular resistance which signifies local inflammation. The two must not be confused. The rigidity of peritonitis cannot be changed in the least by the patient's greatest voluntary effort or the examiner's most gentle palpation.

In meeting the situation presented by any given patient with an acute condition of the abdomen, I believe it most helpful to first ask oneself, "Do the history, symptoms and signs point to an obstruction of some viscus, large or small; to strangulation or thrombosis; to local inflammation; or to peritonitis?" In differentiating we must remember the stages through which each one passes and the possible sequences from one lesion to another. We are not always called in at the beginning and we must reconstruct, from a carefully obtained history, the development and sequence of the lesion or lesions up to the time of the examination.

When we have decided upon the probable lesion and the viscus affected, the next decision is for or against immediate surgery.

Any obstruction except biliary or ureteral obstruction demands immediate surgical relief. These latter, of course, also indicate surgical interference if not spontaneously relieved, but not as an emergency unless the pain continues unabated for more than a reasonable time.

Strangulation or thrombosis always indicates surgery.

Any acute local inflammation, except acute cholecystitis, acute pyelitis and acute salpingitis, requires immediate operation. Some advocate it for acute cholecystitis, but most surgeons believe that the mortality is increased by operation in the acute stage because of difficulty in preventing peritonitis. The acute inflammation will usually recede under conservative treatment with ice bags and duodenal lavage. If improvement is not evident after a very few hours of this treatment, operation must be undertaken. The gallbladder should then be only drained rather than removed, unless it is actually gangrenous. Removal of the acutely inflamed gallbladder increases the risk of peritonitis and septicemia.

The mortality rate from appendicitis has actually been increasing. Ten to fifteen years ago there was revulsion against the surgical popularity of the appendix. This was probably justified, but the pendulum swung too far and many acute cases are now neglected. Wallace[5] reports 600 cases of acute appendicitis, 398 simple ones with .5 per cent mortality, 202 with perforation and 5.5 per cent mortality. Others report a mortality in cases with perforation as high as 14 per cent. Bower and Clark[1] state that 73 per cent of fatal appendicitis cases have received laxatives and that 67 per cent of the deaths are because of the laxatives. They review 1,000 operations for appendicitis, 45 per cent of them with perforation, by fifty-five different surgeons in one year in each of two Philadelphia hospitals (1926 and 1929 respectively), with an overall mortality of 8 and 10 per cent, respectively. If, in the presence of abdominal pain, the appendix can be shown to be tender by any of the methods listed above, immediate operation should be insisted upon.

The fact that ordinary indigestion with gas colic and even enteritis and colitis is often helped by a cathartic has given the laity the habit of taking a cathartic for every abdominal pain. This is disastrous for every surgical condition, and other treatment is also better for gas colic and enterocolitis while the pain lasts. The public should be taught never to take a cathartic in the presence of abdominal pain, but if the pain is not soon relieved by heat and a small enema a physician should be called.

Peritonitis, if of the rare pneumoccous type, has a lower mortality if not operated upon. All other peritonitis I believe is immediately surgical, with conservative surgery indicated, and careful drainage should be instituted along the parietal peritoneum and not between the intestinal loops.

SUMMARY

1. Pain is the chief symptom of the acute abdomen.
2. Sudden onset of pain indicates obstruction of a viscus, strangulation or thrombosis, sudden perforative peritonitis, or gas colic.
3. Intermittent colicky pain indicates obstruction of a viscus, strangulation, intermittent gushes from a perforation, gas colic, or enterocolitis.
4. Steady increasing pain indicates thrombosis, distention, inflammation or peritonitis.
5. Tenderness and muscular resistance indicate inflammation or distention of a viscus.
6. Rigidity indicates peritonitis.
7. Loud peristaltic noises indicate obstruction of the bowel or enterocolitis.
8. The striking tinkle indicates obstruction.
9. Diarrhea indicates intussusception or enterocolitis.
10. Distention of the abdomen indicates paralytic ileus, late obstruction of bowel or late peritonitis.
11. Vomiting had better be disregarded as it may be present in any condition and does not differentiate except when fecal, and then it is too late.
12. Gas colic and enterocolitis are the only two medical conditions to be distinguished from the acute surgical ones. Gas colic can be distinguished from bowel obstruction by the absence of small bowel gas on the scout film. Enterocolitis can be distinguished by diarrhea.
13. Only surgical lesions of the gallbladder, ureters and salpingitis can be temporized with, and only under careful observation.
14. A cathartic is absolutely contraindicated in the presence of abdominal pain.

EXTRA-OCULAR MUSCLE PARALYSIS FOLLOWING SPINAL ANESTHESIA*

K. R. Fawcett, M.D.
Duluth, Minnesota

SPINAL anesthesia for both major and minor surgical procedures below the clavicles has been in use since the beginning of this century, but it has remained for the development of less toxic derivatives of cocain and the introduction of ephedrin to combat the fall in blood pressure to make this type of anesthesia preferable in most instances to the older types of inhalation anesthesia, and thus to popularize it. Complications are rare. A varying degree of circulatory collapse is the earliest one to appear, and probably the most common. The percentage of lung complications, nausea, vomiting and gas pains is definitely lower than is found with inhalation anesthesia. Occasionally postoperative headache is noted similar to the well known spinal puncture headache.

Spinal anesthesia has, however, brought with it one complication that is of especial interest to the ophthalmologist, namely, extra-ocular muscle paralysis. In reviewing the literature, it appears that postoperative palsies are limited almost without exception to the eye muscles. Levine,[1] who has recently published a most excellent monograph on this subject, refers to Blatt,[2] who reviewed the histories of eighty-eight cases and found the trochlear nerve involved in four instances and the oculomotor in six. The remaining seventy-eight involved the abducens, and eighteen of the seventy-eight were bilateral. The interval between the anesthesia and onset of symptoms varied from three days to three weeks. In a large majority of the cases the paralysis disappeared in one to three weeks; in a few it lasted from four to nine months, and in one persisted sixteen months.

From the service of Dr. Babcock, Reber,[3] in 1910, reported five cases of abducens paralysis in a series of 2,000 spinal anesthesias.

No satisfactory reason has been established for the singling out of the extra-ocular muscles as candidates for this peculiar post-anesthetic paresis, nor for the special vulnerability of the external rectus as compared to the other muscles. It is to be noted that the paralysis is often accompanied by other symptoms—photophobia, headache and dizziness appearing rather commonly in case reports, while backache, vomiting, hallucinations, neuroses and tetanic contractures have been occasionally observed. Babcock[4] feels that the cause is a mild infection from the injection of contaminated solutions. He observed that the five cases reported from his service by Reber in 1910 followed the use of imported ampules of tropococaine and stovaine, and states that since discontinuing the use of these ampules he has had no cases of ocular paralysis in the past eighteen years. Evans[5] also feels that the agent is a fault in administration technic, with a resulting meningismus or low grade meningitis. Blanluet and Caron[6] suggest an elective toxic action of the drug, a localized hemorrhage, or a mild meningeal infection. Ricci[7] reported a case with a past history which made him feel the intraspinal injection had stirred up an old chronic serous meningitis. Blatt believes that a neurotic or functional background is a predisposing factor.

There can be little question but that the injected drug often diffuses in appreciable concentration as high as the base of the brain. North and Ferguson, in some experimental work on dogs which has not as yet been published, have shown by the use of dyes that the spinal anesthetic agent frequently reaches the medulla. Thyroid and mastoid operations, even tonsillectomies, have been successfully performed under spinal anesthesia. Anesthesia levels including the chin and lower lip have been reported.

The fact that the paralysis occurs more often with stovaine than with novocaine appears significant. Sollmann[8] states that stovaine is definitely more toxic and very slowly broken down and excreted as compared to novocaine. To me this emphasizes the elective toxic action as the causative agent. As to the peculiar affinity for the sixth nerve, it is to be remembered that the abducens nerve occupies a very superficial position in relation to the fourth ventricle which communicates directly, through the foramina of Luschka and Magendie, with the subarachnoid space into which the anesthetic is injected.

---

*From the Duluth Clinic. Presented before the St. Louis County Medical Society, December 11, 1930.

Koster and Weintrob[9] call to attention the animal experiments of Van Lier,[10] who demonstrated swelling of the nucleus of the ganglion cells after spinal anesthesia, and suggest a possible degeneration of the ganglion cells as a cause of abducens paralysis.

If the paralysis is due to a mild meningitis, it would appear that strabismus should be a much earlier and more common symptom of specific meningitis. It has also been my observation that strabismus, when it is seen in a specific meningitis, is usually divergent, while the usual type following spinal anesthesia is convergent.

I wish to present two cases of unilateral abducens paralysis following spinal anesthesia. The first is very characteristic of the short course and rapid, unaided recovery which usually occur in this condition. The second has proved very disturbing—both to the patient and to us.

Case 1.—Mrs. E. W., white, aged 46, was given spinal anesthesia for a diagnostic curettage on September 18, 1930. One hundred mgm. of novocain were injected, and ephedrin was given simultaneously to maintain satisfactory circulatory tone. The operation and postoperative recovery were uneventful, and the patient was discharged from the hospital on the fourth day. On the thirteenth day after operation, the patient suddenly developed diplopia, accompanied by slight photophobia, vertigo, and headache. Examination showed a paralysis of the right external rectus muscle. Eye movements otherwise were normal, and the vision of each eye was 20/20. There was no past history of strabismus. The patient was given a good prognosis without being too specific as to intervening time. Therapy consisted simply of covering one eye alternately for half day periods to relieve the diplopia. On the thirteenth day the paralysis had entirely disappeared, and ocular rotation was complete. The patient has had no further trouble.

Case 2.—Mrs. L. T., white, aged 42, was operated upon for fibroids on May 20, 1929. A hysterectomy and appendectomy were performed. One hundred and fifty mgm. of novocaine were injected intraspinally, and ephedrin given hypodermically as in the preceding case. The operation was uneventful. Convalescence was a little slow. On the twelfth day postoperatively the patient developed diplopia, and examination showed complete paralysis of the left external rectus muscle. Shortly after this, the patient left the city, and we were unable to study and observe her further. However, the diplopia continued. A recent examination at her home showed a persisting strabismus. However, she states that the diplopia is no longer constant, and with the right eye covered she is able to rotate the left eye laterally about twenty degrees. The paralysis has now persisted for seventeen months. The patient is naturally rather discouraged and informed me that a doctor she had consulted while out of town had advised a muscle shortening operation. However, I feel that there has been some improvement, and believe that the patient should wait another six months at least before considering operation.

CONCLUSIONS

1. Extra-ocular muscle paralysis is a rare complication of spinal anesthesia, but must nevertheless be kept in mind constantly by the surgeon and ophthalmologist.
2. The etiology has not yet been definitely established.
3. The onset of symptoms varies from three days to three weeks.
4. In a large majority of the cases the symptoms clear up spontaneously within three weeks.
5. The treatment should be extremely conservative, and muscle operation certainly should not be resorted to under eighteen months.

ALLERGY, ANAPHYLAXIS AND HYPERSENSITIVENESS*

Albert V. Stoesser, M.D., Ph.D.
Minneapolis

ALLERGY, which means altered reactivity, is a term introduced by Von Pirquet and Schick[20] at the time they were studying serum sickness, a condition which exists in many individuals after receiving therapeutic serums. Doerr[7] later used the term to apply to all phenomena of hypersusceptibility in animals and in man, and Zinsser[23] also was in favor of using the word allergy to designate this interesting field of medicine. We find, however, under the general heading, allergy, the existence of a great deal of confusion when any attempt is made to classify and correlate the various experiments with animals by numerous workers and the clinical observations of many physicians.

The terms anaphylaxis, allergy and hypersensitiveness are used interchangeably in the medical literature. An effort has therefore been made at this time after a careful survey of the reports of some of the leading observers in this field to present a classification or outline with the hope that it will be of some value in the diagnosis and possibly in the prognosis and the treatment of allergic conditions.

CLASSIFICATION OF ALLERGY

I Anaphylaxis or anaphylactic hypersensitiveness
  A. In animals—experimental
  B. In man—anaphylactic shock in a previously sensitized individual
  C. Drug anaphylaxis in man
II Human or natural hypersensitiveness
  A. Serum allergy (or sickness)
  B. Drug allergy (or idiosyncrasy)
  C. Atopy or atopic hypersensitiveness
    1. Eczema
    2. Allergic coryza due to
      a. Inhalants
        (1) Animal emanations
        (2) Pollens (hayfever or pollinosis)
        (3) Powders and perfumes.
      b. Foods and drugs
      c. Bacterial products of infection
    3. Bronchial asthma due to
      a. Inhalants
      b. Foods and drugs
      c. Bacterial products
    4. Other conditions which are still questionable
      a. Urticaria, and some forms of dermatitis and pruritus
      b. Food allergy
      c. Allergic migraine
      d. Purpura (Henoch's)
      e. Some cases of epilepsy
  D. Serum and drug shock in the atopic individual
III Hypersensitiveness in infection
  A. Bacterial allergy or hyperergia. Certain manifestations in the following diseases:
    1. Tuberculosis
    2. Rheumatic fever
    3. Scarlet fever
    4. Nephritis
    5. Lobar pneumonia
  B. Fungous and parasitic infections may be accompanied by allergic reactions

The first large division under allergy is anaphylaxis or anaphylactic hypersensitiveness. This subject has been carefully reviewed and defined by Wells.[21] He states that much confusion exists in the literature because of the loose use of the term anaphylaxis to cover a multitude of conditions. In order to have anaphylaxis we must have the animal sensitized by a substance called an antigen which is a soluble protein foreign to the circulating blood of the animal and capable of producing immune bodies in the blood of the animal when injected. These immune bodies are called antibodies and they reach their peak of production about 7 to 10 days, or more, after the injection of the antigen. Then when the antigen is reinjected there is a specific union of the antigen with the antibodies in the tissues, giving rise to an anaphylactic reaction or shock.

---

*From the Allergy Clinic, Department of Pediatrics, University of Minnesota.

In true anaphylaxis, the non-striated muscle, especially the uterine muscle, from a sensitized animal will if removed from the body and placed under suitable conditions be found to give strong contractions when brought in contact with even very dilute solutions of the specific antigen. Furthermore, the state of sensitivity can be passively transferred in many cases to another animal. Then, too, in anaphylaxis the observation has been made that there is a loss of sensitivity after anaphylactic shock if the animal survives. This is the refractory period during which there exists a condition of specific desensitization.

Up to the present time, there is no conclusive evidence that would indicate that heredity plays any part in anaphylaxis. Monkeys and man are hard to sensitize when a comparison is made with such animals as the guinea pig, rabbit and dog. This means that only a small proportion of the population are sensitized when receiving a foreign serum such as tetanus or diphtheria antitoxin.

Occasionally an individual lends himself to an easy sensitization, and then upon receiving the second injection in the form of some therapeutic serum he goes into true anaphylactic shock, especially if the injection is made intravenously. Like an animal, he becomes desensitized after this reaction, although sensitivity may gradually return.

Desensitizing the anaphylactic sensitive individual before the administration of serum is rather difficult. Larson[12] states that it can be accomplished if a small amount of the preparation (antitoxin) is injected intravenously every twenty minutes, or intraperitoneally every four hours, or subcutaneously every twenty-four hours. Injecting a small amount of the material subcutaneously and waiting only one-half hour is not safe.

Drug anaphylaxis in man includes both the local and systemic reactions to various drugs. Wolff-Eisner[22] thought that these reactions might be produced by the blood or tissue proteins altered by the chemical which the individual received. These altered protein compounds act the same as foreign proteins and are capable of sensitizing man or animal in some cases.

Before leaving anaphylaxis it may be of interest to note that it is easier to produce anaphylactic shock if the hydrogen ion concentration of the blood is shifted to the acid side of the normal range and kept there. A shift to the alkaline side makes it more difficult to have an anaphylactic reaction.

Next, the second division of allergy (see classification) may be considered. Human or natural hypersensitiveness is of special interest to the clinician and first consideration will be given to serum allergy. This condition was carefully studied by Von Pirquet and Schick and is quite common. About five to fifteen days after the administration of a serum there appears an urticarial eruption or rash with or without fever, joint pains and general prostration. The reaction is thought to be caused by an interaction between the antigen and the antibodies which have been produced. In this way there is a close connection with anaphylaxis and some observers have called it a delayed anaphylactic reaction, but others have stated that there is no conclusive evidence of the antigen-antibody union and the condition is not anaphylactic.

In regard to drug allergy, some chemicals are capable of producing symptoms similar to those found in serum allergy. For example the chemical compound, phenyl-ethylhydantoin (commonly called nirvanol) is used in the treatment of chorea, and in many individuals it gives rise to a typical series of symptoms. After about 7 days of administration, there is a sudden onset of fever and about two days later an eruption appears. The patient is quite uncomfortable. Blood examination may reveal an increased number of eosinophiles.

Human hypersensitiveness also includes that group of allergic diseases to which Coca[5] gave the name atopy, which means "a strange disease." From this, the term atopic hypersensitiveness has been derived. Coca included all those clinical forms of hypersensitiveness which occur so far as is known only in human beings and which are subject almost entirely to inheritance.

The clinical forms included in this category are hayfever and asthma, and possibly eczema. More information may lead to the addition of such conditions as urticaria, and some forms of dermatitis and pruritus, food allergy, allergic migraine, purpura (Henoch's) and some cases of epilepsy.

The substances to which the atopic individual responds in an abnormal way are called atopens, and they may be proteins or non-proteins. They react with specific bodies found in the blood of nearly all atopic persons. Whether these bodies which have been called atopic reagins are true antibodies developed immunologically under antigen stimulation or physiological products like the natural hemo-agglutinins and hemolysins is not known.

In atopic hypersensitiveness, heredity seems to play an outstanding part. Coca states that by the tenth year of life atopic symptoms have appeared in 72 per cent of the atopic offsprings under a bilateral hereditary influence, in 35 per cent of those subject to a unilateral influence, and in only 20 per cent of those with a negative family history. Bray[3] says that asthma and related conditions are transmitted as a Mendelian dominant. The greater the heredity the earlier are symptoms manifested and the earlier in life the individual becomes sensitive the greater the tendency to multiple sensitization.

The atopic individual may respond with a marked reaction when receiving a therapeutic serum, especially if it is given intravenously. The same thing may occur if certain drugs such as the arsenicals are given to these people. This phenomenon may be referred to as serum and drug shock in the atopic individual (see classification). According to Lamson[11] this is not due to anaphylaxis although clinically the shock can hardly be differentiated from a true anaphylactic reaction in a previously sensitized person.

Desensitization of the atopic sensitive individual with the subsequent injection of the foreign substance is, as in anaphylaxis, not such an easy procedure. The most concentrated serum obtainable should be used and first injection should be made subcutaneously. According to MacKenzie and Hanger[14] it should not be more than 0.01 c.c. If no symptoms develop, the dose may be doubled every thirty minutes until 1 c.c. is given. Then the next injection may be 0.1 c.c. intravenously, and every twenty minutes thereafter the intravenous dose may be doubled until the required amount of serum has been given.

It may be interesting to note at this time that in the atopic individual any drug or diet which tends to shift the hydrogen ion concentration of the blood to the acid side within the normal range decreases in some cases the tendency to allergic reactions. This is just opposite of the conditions which have been observed in case of anaphylaxis.

There has, however, been an effort made to consider anaphylaxis in the animal and hypersensitiveness in man as due to the same fundamental cause, with man responding not exactly in the same way as the animal because he is a more highly differentiated subject in which the allergic mechanism plays its part.

Topley and Wilson[19] state that the differences between anaphylaxis and human hypersensitiveness are only the result of an incomplete study and quote Doerr as pointing out the fact that we have studied natural hypersensitiveness only in man and anaphylaxis only in the experimental animals, so that it is at least possible that the differences which have been noted are referable in a large part to the restricted universe selected for study.

Ratner and Gruehl[16] have since reported experiments in which they have been able to show that the blood of a human asthmatic and the blood of an asthmatic guinea pig can passively sensitize the normal human skin and normal guinea pigs. From this they believe that their results indicate that hypersensitiveness in man and anaphylaxis in lower animals are fundamentally dependent on a common anaphylactic antibody and that the distinction between anaphylactic antibody and the atopic reagin is untenable.

Finally the third division (see classification) may be briefly discussed. Hypersensitiveness to infection represents another interesting field for further investigation. In the first place, bacterial allergy or hyperergia indicates an increased capacity of the tissues to react to the bacterial products of living organisms localized in some part of the body, or to react to the disintegration products of the dead organisms or of the infected tissues in the focus. The allergic state may in certain instances be regarded as an index of resistance, a thing which some believe to be true in the case of tuberculosis. Krause[10] and Pottenger[15] have considered allergy as representing part of the protective mechanism of the tuberculous infected individual.

Recently, however, Rich[17] states that in spite of the fact that bacterial allergy operates to destroy the invading organisms and plays an accessory rôle in certain infections, the present state of information in regard to tuberculosis does not warrant the use of the term allergy to indicate resistance in tuberculosis. Branch and Cuff,[2] after studying carefully the allergic, anaphylactic and immune reactions in guinea pigs following inoculation with heat-killed tubercle bacilli, conclude that allergy and anaphylaxis in tuberculosis are independent phenomena, and immunity may be present without allergy. Furthermore they believe that the development of allergy appears to be interrelated with the process of caseation.

Some observers believe that an allergic reaction takes place in acute rheumatic fever. The streptococcus present in a focus in the human body sensitizes certain tissues, and the joint manifestations of rheumatic fever represent a maximal response of the hypersensitized tissue to a minimal stimulus. Swift and Derick,[18] Birkhaug,[1] Clawson,[4] and others have studied the possibilities of the application of the theory of allergy to the bacteriological problems of rheumatism.

Cooke[6] believes that certain of the manifestations present in scarlet fever may be explained on an allergic basis. Longcope[13] and his colleagues[8] have found positive skin tests to the streptococcus in some individuals suffering with acute glomerular nephritis. This might indicate that the kidney manifestations were an allergic response on the part of kidney tissue highly sensitized to the streptococcus which might be localized in a distant focus, such as the tonsil. Then, too, lobar pneumonia caused by types one and two pneumococcus has been considered in part as an allergic phenomenon.

Certain fungous and parasitic infections are accompanied by allergic reactions. For example, it has been shown that with an extensive thrush infection of the gastro-intestinal tract there may be a skin eruption resembling a severe weeping eczema. This condition has been considered by many as an allergic phenomenon and this same opinion is held by Henrici.[9]

With this classification of allergy the author has made no attempt to discuss in detail the various divisions and subdivisions but only has offered a few remarks in explanation. The field of allergy with all its phases is certainly of great interest, and it is hoped that further work in this field will lead to a simpler classification. At the present time a review of the writings of investigators does not permit this.

CASE REPORTS

SUBCUTANEOUS EMPHYSEMA FOLLOWING ASPIRATION OF FOREIGN BODY

REPORT OF THREE CASES*

Porter P. Vinson, M.D.
and
Herman J. Moersch, M.D.
Rochester, Minnesota

Forbes, in 1926, described the preoperative occurrence of emphysema of the neck and thorax of a child, aged two years and nine months, three days after aspiration of a portion of nut. Except for this report, we have not been able to find any reference to a similar complication. In a comprehensive article on the symptoms and signs of foreign bodies in the bronchi, McCrae stated that the escape of air from the lung into the mediastinum is not uncommon following aspiration but he did not mention the possibility of the development of subcutaneous emphysema. Because of the apparent rarity of this complication, the following cases are presented.

Case 1.—A boy, aged six years, aspirated a small metal paper clip, January 19, 1930. Five hours after aspiration, there was dyspnea and substernal pain with elevation of temperature to 101.8° F. Roentgenograms of the thorax revealed the foreign body in the right bronchus with partial atelectasis of the right lung.

The child was brought to The Mayo Clinic for examination twenty-one hours after the foreign body had been aspirated and in addition to the roentgen-ray evidence of the foreign body in the lung with partial obstruction in the bronchus, there was a moderate amount of subcutaneous emphysema over the anterior portion of the thorax and neck on the right side (Fig. 1). Bronchoscopic examination revealed the foreign body in the right bronchus and it was removed without difficulty (Fig. 2). The following day, the emphysema had disappeared, and the temperature had returned to normal. The child was dismissed from observation January 23. A letter received from the parents a year later stated that the child was perfectly well.

Case 2.—A boy, aged three years, had been well until the evening of December 24, 1930, when he choked while eating peanuts, but because he was held upside down at the time of the accident and several pieces of nut came out of his mouth it was assumed that none was aspirated. Following this, he was rather listless and had a little cough and fever until the evening of January 4, 1931, when marked swelling of the head and neck occurred after a severe coughing spell. These paroxysms of coughing recurred with increasing swelling of the head and neck and a physician was consulted. Evidence of obstruction in the right main bronchus with marked subcutaneous emphysema was found. Roentgenograms of the thorax revealed an emphysematous condition of the upper portion of the right lung with atelectasis of the lower portion, air in the pericardial cavity, and pronounced emphysema of the tissues of the head, neck, upper portion of the thorax and arms (Fig. 3).

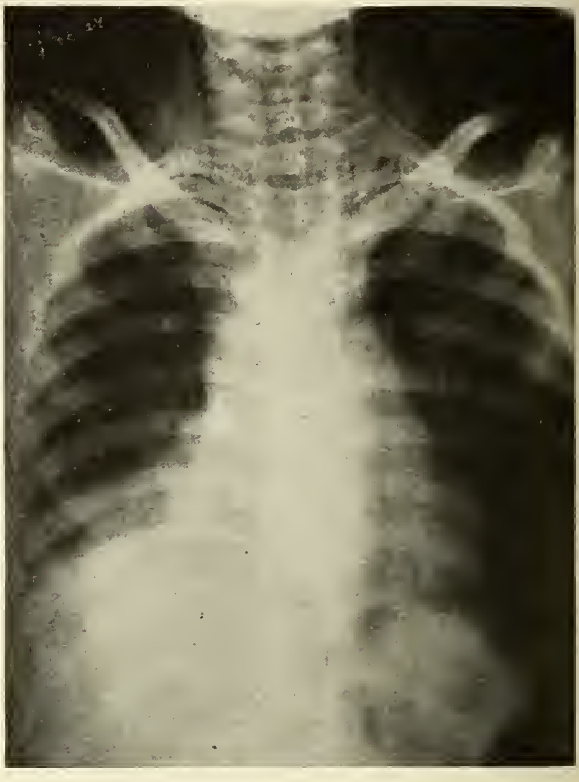

Fig. 1 (Case 1). A paper clip in the right bronchus. Emphysema in the tissues of the neck may be noted.

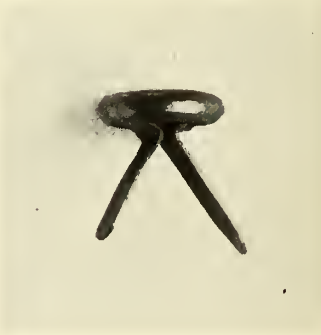

Fig. 2 (Case 1). Paper clip removed at bronchoscopy.

---

*From the Division of Medicine, The Mayo Clinic, Rochester, Minnesota. Submitted for publication February 18, 1931.

The child reached the clinic for treatment late in the afternoon of January 5, 1931, in a critical condition. A bronchoscopic examination was made immediately and a peanut kernel was found in the right main bronchus. The foreign body was grasped with forceps and, as it was too large to be removed through the bronchoscope, it was brought up to the end of the tube and was withdrawn with the tube and forceps. Examination of the foreign body, after removal, disclosed that it consisted of a portion of a kernel only, but as air now entered both lungs normally, it was considered inadvisable to reintroduce the bronchoscope because of the danger of producing laryngeal edema. The child was admitted to an oxygen chamber immediately after bronchoscopy, and the following morning the remainder of the nut was expelled spontaneously. Recovery was uneventful and the patient was dismissed January 9. At the time of dismissal, there was scarcely any air in the subcutaneous tissues, there had been marked restoration of the lungs to normal and the amount of air in the pericardial cavity had greatly diminished (Figs. 4 and 5). In every other respect, the child seemed well. A letter from the parents two weeks later stated that he was in good health.

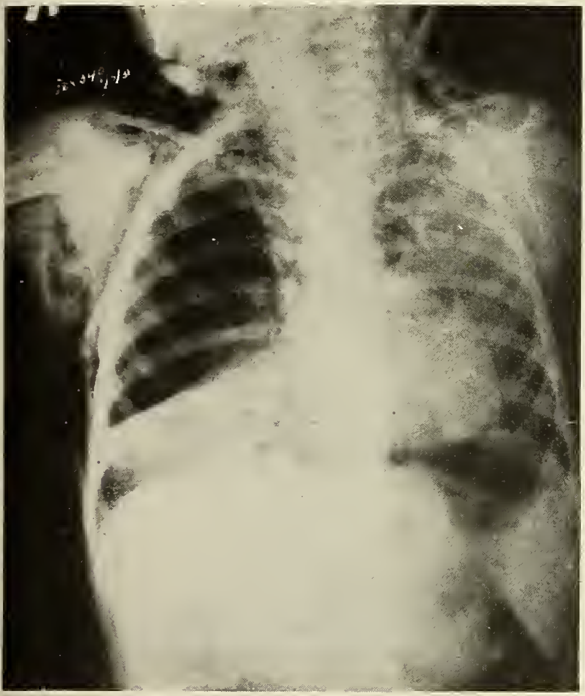

Fig. 3 (Case 2). A peanut in the right main bronchus, with emphysema of the upper part of the right lung and atelectasis in the lower part, marked subcutaneous emphysema of the tissues of the neck and thorax and apparent pneumocardium.

Case 3.—A girl, aged two and a half years, aspirated a peanut kernel January 19, 1931. She seemed comfortable for two days, when fever and cough developed and it was thought that she had penumonia. January 24, swelling of the upper part of the thorax and neck developed that gradually increased with each spell of coughing. The patient was brought to the clinic soon after the development of the swelling. Almost complete obstruction to the passage of air into the right lung, and marked subcutaneous emphysema of the tis-

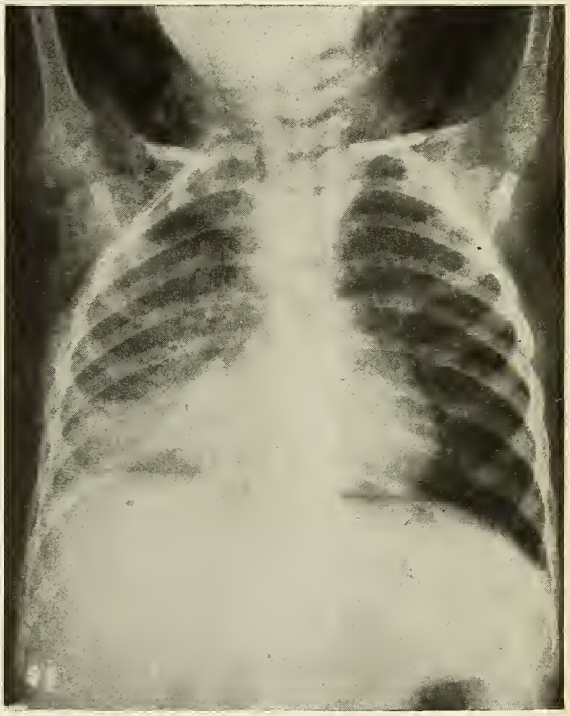

Fig. 4 (Case 2). The thorax after removal of the foreign body. The emphysema of the upper portion of the right lung is no longer apparent; the infiltration of the lower portion of the lung is greatly reduced, and there is much less air than before bronchoscopy.

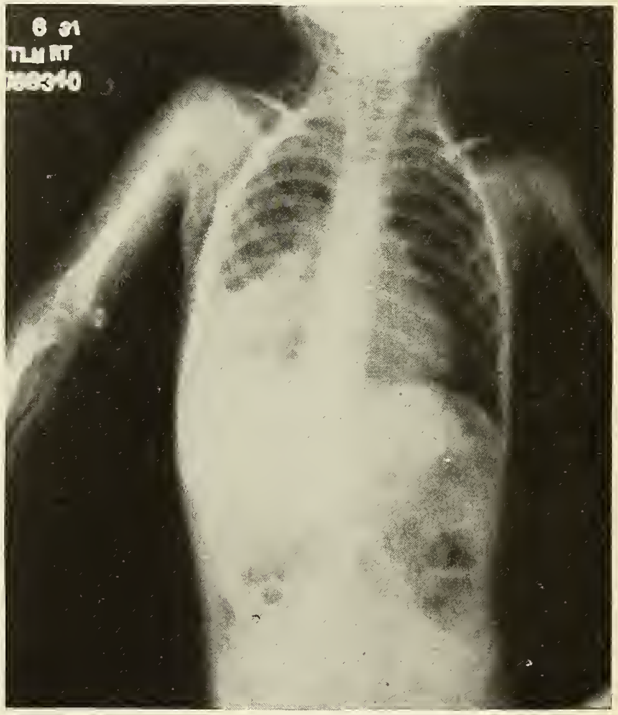

Fig. 5 (Case 2). Air is shown extending into the tissues of the forearm.

sues of the head, neck and upper portion of the thorax were found.

It was considered unwise to delay removal of the foreign body and roentgenograms of the thorax were not made. Bronchoscopic examination disclosed a large portion of peanut kernel in the right main bronchus and it was removed. The child was placed in an oxygen chamber immediately after the removal of the foreign body, but in spite of this it was necessary to open the trachea after twenty-four hours. There was practically no reaction associated with the tracheotomy and after five days the tube was removed. The patient was dismissed February 2. The emphysema had disappeared completely, and the child seemed perfectly well.

COMMENT

In the first case, it was assumed that the sharp point of the paper clip had been forced through the wall of the bronchus during a paroxysm of coughing and that this had permitted the escape of air into the mediastinum with the subsequent development of subcutaneous extravasation.

In the second and third cases, the foreign body evidently was of just the proper size to permit the passage of air into the distal bronchi on inspiration, but to have closed the bronchus on expiration. This resulted in obstructive emphysema and air was forced from a ruptured emphysematous bleb on the surface of the lung into the mediastinal structures and then into the subcutaneous tissues. In the second case, it is very difficult to explain the apparent presence of air in the pericardial cavity.

OMENTAL CYST IN A CHILD*

Oswald S. Wyatt, M.D., F.A.C.S.
Minneapolis

The following case I wish to report, with a brief discussion, because the condition is rather uncommon, and the diagnosis is unusually difficult. This omental cyst, which we did not diagnose, presented the unusual feature of rupturing, which made the picture still more obscure.

Ladd in the American Journal of Diseases of Children for 1926 briefly surveyed the literature and up to that date only about forty-five cases had been reported.

The condition is usually diagnosed as tuberculous peritonitis of the ascitic type, ascites, hydatid cyst, ovarian cyst, cystic kidney, mesenteric cyst or enteric cyst. When the cyst has ruptured, as in this case, the most likely diagnosis is primary peritonitis or perforated appendix with peritonitis. At least the picture is one of an acute surgical abdomen.

By way of differentiation, patients with large cysts usually present dullness over the entire front of the abdomen. A bismuth meal in the intestinal tract might show the fluid to be accumulated in front of the intestines. If paracentesis reveals a chylous fluid containing broken down red blood cells, it should suggest a lymphatic cyst, which might be of omental or mesenteric origin.

A cystoscopic examination should rule out a cystic kidney.

Bimanual examination, with one finger in the rectum, should rule out small ovarian cysts, especially in young children.

Negative tuberculin tests should rule out tuberculosis.

If the cyst is very mobile it should bring to mind the possibility of an omental cyst.

The treatment of this condition is surgical, the results should be good, and the risk slight.

Halsted reported, in the Johns Hopkins Hospital Bulletin of 1920, a case of omental cyst. The patient was a female child, two years of age, who had been tapped for ascites. The point which he wished to stress was that whenever a child comes under observation with abdominal distension, the possibility of lymphatic cyst should be borne in mind. He saw his patient again at the age of twenty-four, married and in good health.

CASE REPORT

The patient, a female child, three and a half years of age, when last seen by Dr. E. F. Robb, about one year ago, was a healthy, well developed, well nourished, normal child. On January 8, 1931, about 3 p. m., the child began to compain of abdominal pain, which the mother did not think was very severe. About three hours later the child vomited, the only time she did vomit during the illness. She ate supper that evening. Later the mother gave her an enema with constipated results. The child continued to complain of abdominal pain until about midnight, then fell asleep and slept very well for four to five hours. On the morning of the 9th, the child still complained of abdominal pain and refused breakfast and lunch. About 2 p. m. the pain became very severe. Two hours later the temperature was 104 degrees and her abdomen presented a board-like rigidity.

Tenative diagnosis: Perforated appendicitis with generalized peritonitis.

Operation: Upon opening the abdominal cavity a large amount of light green fluid (estimated at about 1,000 c.c.) was encountered in the peritoneal cavity. The peritoneum was moderately inflamed and I thought at first that we were dealing with a primary peritonitis. Upon further examination a large mass was felt, which at first appeared to be a large intussusception with gangrenous bowel. Upon more complete exposure it was found that the mass was a large multilocular cyst contained within the great omentum. When the cyst was delivered outside the abdomen it was about as large as an infant's head. One of the cysts had ruptured, accounting for the free fluid and the peritonitis. The cyst originated high on the omentum, close to the transverse colon. The cyst was partially extirpated, the omentum clamped at the base and the cyst very easily removed. The gallbladder, stomach, and duodenum appeared normal. The appendix was removed. No cysts were seen in the pelvis. The abdominal wall was closed in layers, with a Penrose drain to the pelvis.

---

*Read before Janney Children's Hospital Staff, Minneapolis, March 3, 1931.

Upon opening the remaining cyst perhaps another quart of dark, greenish fluid was obtained, which chemically proved to contain blood pigment.

Postoperative diagnosis: Multilocular omental cyst.

Pathological report, by Dr. J. S. McCartney: The tumor of the omentum is a collapsed cystic mass eighteen by six and five-tenths by three and five-tenths centimeters; it is composed chiefly of two large cysts and one small one. One of the large cysts has a hemorrhagic lining. The lining of the other large cyst is pale. The large cysts have trabeculated inner surfaces. In the omentum at a point about five centimeters from the main mass are two other cysts, each about one centimeter in diameter. Section of the cyst with the hemorrhagic wall shows an indistinct endothelial lining and a marked subacute inflammation beneath this endothelium. Section of the wall of the pale cyst shows very definite endothelial lining, but no evidence of inflammation. No epithelium is found in any of the sections. The diagnosis is cyst of the omentum probably of lymphatic origin.

These cysts are lymphatic in nature, and probably congenital in origin.

MEDICAL ARTS BUILDING.

THROMBOPLASTIN HYPODERMIC-SQUIBB OMITTED FROM N.N.R.

Thromboplastin Hypodermic-Squibb is a sterilized extract of cattle brain in physiologic solution of sodium chloride intended for hypodermic injection to increase the coagulability of the blood. The Council on Pharmacy and Chemistry first accepted thromboplastic substances in 1915. Since then little or no additional evidence has developed for the value of these preparations: their intravenous use almost certainly presents dangers, and the Council has become convinced that there is no satisfactory evidence for their effectiveness when injected subcutaneously. In view of this the Council decided, unless new evidence should appear, not to include hereafter in New and Non-official Remedies any preparation of this type except for local application. Since Thromboplastin Hypodermic-Squibb is intended for hypodermic or subcutaneous injection, E. R. Squibb & Sons were informed of the action of the Council and asked to submit evidence in support of the value of the hypodermic administration of thromboplastic substance. The submitted evidence did not permit a revision of the Council's conclusion that the hypodermic or subcutaneous administration of Thromboplastin Hypodermic-Squibb or of other thromboplastic substances is not therapeutically valuable and therefore omitted the Squibb preparation from New and Non-official Remedies. (Jour. A. M. A., February 21, 1931, p. 613.)

PRESIDENT'S LETTER

IN an association like ours, with its multiple interests partaking equally of scientific advancement and public obligations, some liaison officer between the individual society and its various official activities is highly desirable.

We have such liaison officers in our councilors. They know the business of the organization intimately. They can supply the color and intent back of the dry, uncolored reports of official conferences and delegates' meetings that are all that otherwise reach remote county societies. They could be used to knit us all much more intimately and solidly together in spite of our scattered far-flung situation. The question is, why don't we use them?

When the councilors met at the May meeting of the Association in Minneapolis, several reported there that their councilor duties were curiously restricted. They could not keep their districts properly informed. They could not suggest or advise. They were not so invited. Of course the reason was not that the societies in question disliked inviting councilors to their meetings. Probably the societies in question entirely overlook the fact that there are councilors in their districts.

The House of Delegates meeting in Minneapolis was packed to overflowing with important business, vital business about which every member of the association should have an intimate knowledge. House of Delegates' decisions and reactions to decisions, this ye and the next and the next, are going to affect the practice of medicine very vitally in these changing troublous times in Minnesota. Are all of the members of our great organization going to be satisfied with the clipped, official accounts of resolutions passed and committee reports accepted?

The councilor of your district took an active part in the transaction of the business of the last meeting. Invite him in to tell you about it. Never mind how busy he is. When he accepts his important post he is prepared to make personal sacrifices in the interest of the profession. He will be glad if you call on him. It will be eminently worth your while.

Witness the report of one of the new members of the Council, O. J. Hagen of Moorhead, submitted at the May Council meeting. Dr. Hagen had more invitations to visit societies in his district than he was able to accept, since several of the dates conflicted. Since early in 1931, however, when he took office, he visited the Clay-Becker Society, the Park Region Society and the Red River Valley Society.

"In Clay-Becker there is manifested a healthy coöperative interest in both the scientific and public aspects of the medical profession," Dr. Hagen reported. "A special meeting was called to discuss the legislative problems of the association that arose during the legislative session so that a local viewpoint might be intelligently expressed. This showed a wholesome trend. It helps so much to crystallize the profession into a compact unit of thinking and performance."

Of the Park Region meeting, Dr. Hagen said: "The scientific meeting was of a high order; the discussion on increasing the membership sensible; the fine spirit of comradeship encouraging."

Of the Red River Valley Meeting: "These giants of the North have always given a large contribution to medicine in its highest sense; they are intensely alive to problems of legislation and public health.

"I am confident that the Eighth District is in a healthy state of cultivation and that they will continue to make their contribution in the future as in the past a very, very impressive one."

Here is an example of a valuable relation between a councilor and his district. It should prevail everywhere throughout our association.

And don't forget that there is another new and particular service your councilor can perform for you this year. Two new studies, one on medical economics and the other on industrial practice, have been added to the state program for the new year. The time has come, as you know, in the practice of medicine in America, when the physician can no longer leave it to chance or the lay economist or the ambitious welfare worker to determine upon reforms in the system of caring for the sick.

These studies undertaken by our own members will provide us with authentic reliable information about conditions in our own state, information that must be the basis of all the future public policy of our societies.

The two committees who will carry on the work were appointed by the Council. The Council and therefore your councilor will be constantly informed on their findings.

Why wait to get such information second hand?

L. Sogge

President
Minnesota State Medical Association.

Vol. XIV July, 1931 No. 7

THE EARLY DETECTION OF TUBERCULOSIS

While the mortality from tuberculosis has been halved in the past decade, it is common knowledge that there has been little or no reduction in this mortality among girls in the teen age. The infectiousness of the disease, mode of transmission, and the frequency of childhood infection are well understood, and yet prevention of infection is far from satisfactory.

In the interests of early detection of tuberculosis, the National Tuberculosis Association, of which the Minnesota Public Health Association is a component part, is advocating universal investigation of school children by means of the Mantoux tuberculin test and X-ray examination of the lungs in positive reactors. This presupposes a practically 100 per cent accuracy for the Mantoux test and a universal agreement as to the interpretation of lung shadows in children. It is perhaps needless to state that a diagnosis of the presence of active tuberculosis which depends on these two methods alone is unreliable. History, physical examination, and sputum analysis are still indispensable.

Groups of school children in Minnesota have been and are being investigated by various local agencies to determine the incidence of positive Mantoux reactors and undetected tuberculosis. An occasional case of active tuberculosis has been discovered in various localities.

The importance of picking up unsuspected active tuberculosis by every possible method cannot be over-estimated. Even though these surveys tread on the toes of private practice, the practitioner will not object to such a method if it is the only practical way to detect unrecognized cases. An individual with undetected active pulmonary tuberculosis is nobody's patient at a time when diagnosis is all-important. Whether the surveys mentioned should be extended to provide for universal free examinations for tuberculosis is open to some question.

Some doubt has been expressed as to the value of a positive tuberculin reaction in selecting individuals for further investigation. Eberson, Delprat, and Wolff,[*] while recognizing the value of tuberculin and the X-ray in the diagnosis of pulmonary tuberculosis, concluded from a study of groups of positive and negative tuberculin reactors that tuberculin cannot be counted on to exclude the non-tuberculous. The authors report, too, that single findings of hilus calcification, increased lung markings, enlarged bronchial lymph nodes and peribronchial infiltration as shown by the X-ray plate occurred more often in the group not reacting to tuberculin. Certainly there is no agreement at present in the interpretation of hilus shadows in childhood.

---

[*] Eberson, F., Delprat, Jessie P., and Wolff, E.: Suspected juvenile tuberculosis. Am. Jour. Dis. Child., 40:753 (Oct.), 1930.

The manner in which a survey of this sort is conducted is very important. All human beings are concerned to some degree about their physical well-being—children as well as adults. Perhaps most of us have just a little neurotic tendency. To be told that a skin test shows a tuberculous infection may not be the best thing in the world for many individuals. To be told further that an X-ray of the lungs is advisable because of the skin test and then that the X-ray is not normal (and how often calcified hilus areas are reported) is only too likely to bring out neurotic tendencies. A survey of apparently normal individuals should provide that findings be reported to medical advisors for evaluation. Their significance should be determined in conjunction with the history and physical examination by the attending physician. By this means only will a false diagnosis of tuberculosis be prevented and needless treatment avoided. Who knows but what a positive tuberculin reaction is indicative of a vaccination and of increased resistance to further infection?

"DOC" WILLIAMS

The passing of "Doc" Williams recalls the colorful career of one of Minnesota's prominent physicians. His name will be handed down in the annals of athletic history in connection with his outstanding activities at the University of Minnesota. He was a physician who found time to do more than practice medicine and to do that something well.

A Yale athlete of outstanding ability in track as well as football, he continued his interest in athletics continuously after graduation; as coach to preparatory schools and for a brief period at West Point. When Minnesota with plenty of material but scant football coaching was unheard of in collegiate athletics, he put the university on the football map by developing such all-Americans as Johnny McGovern, James Walker, and Bert Baston.

"Doc" Williams acquired national prominence in football circles through his famous Minnesota shift. He helped organize the American Intercollegiate Athletic Association and proposed the rule which introduced the forward pass into the game. The same vigor and punch which he instilled into his men he exhibited in his interest in the game, and success was his.

OF GENERAL INTEREST

Dr. A. R. Johnson, formerly of Eveleth, Minnesota, is now located at Isanti, Minnesota.

Dr. O. E. Sarff, formerly located at Baudette and Warroad, is now practicing at Roseau, Minnesota.

Dr. Frank Grawn, formerly of Duluth, is now practicing at Northome, Minnesota.

Dr. Bernard E. O'Reilley has opened offices at 1267 Lowry Medical Arts Building, St. Paul, and is specializing in eye, ear, nose, and throat diseases.

Dr. Donald A. Dukelow after June 15 will be located at St. Charles, Minnesota. Dr. Dukelow was formerly associated with the Mayo Clinic at Rochester.

On May 19, 1931, the following officers of the Minnesota Pathological Society were elected: Dr. J. F. Noble, president; Dr. J. S. McCartney, vice president; Dr. E. F. Bell, secretary-treasurer.

Announcement has been received of the association of Dr. Arthur E. Perley, formerly of the Nicollet Clinic, Minneapolis, with Dr. Harold Swanberg of the Quincy X-ray and Radium Laboratories, Quincy, Illinois.

The offices of the Minnesota State Board of Examiners in the Basic Sciences have been moved from 110 Anatomy Building to 126 Millard Hall, University of Minnesota, Minneapolis. Dr. J. C. McKinley is secretary-treasurer of the Board.

Dr. Ivar Sivertson of Minneapolis was appointed a member of the State Board of Medical Examiners for a term ending May 1, 1938. He succeeds Dr. C. E. Kaine of Morris. The appointment was made by Governor Olson upon recommendation of the State Medical Association.

The following were elected Affiliate Fellows of the American Medical Association at the Philadelphia meeting: S. S. Hall, Minneapolis; L. K. Onsgard, Houston; E. S. Strout, Minneapolis; Chas. A. Van Slyke, Saint Paul; Ed. H. Whitcomb, Saint Paul; Warren Wilson, Northfield; W. F. Wilson, Lake City.

According to a newspaper report, hospitals operated by the Northern Pacific Railway Beneficial Association cared for 33,667 patients in 1930. The total number of hospital and non-hospital cases amounted to 76,089. Hospitals are operated in Glendive, Missoula, Tacoma, and Saint Paul. Some 17,935 patients were treated by the Saint Paul unit.

Dr. Richard E. Scammon, who left the University a year ago to become dean of medicine and biological sciences at the University of Chicago, will return in the fall to be dean of medical sciences, a new position created by the Board of Regents. Dr. E. P. Lyon will continue as dean of the medical school while Dr. Scammon's duties will include stimulating interest in medical science in the other departments of the University as well as in the medical school.

The Millard Memorial Fund being collected by the Minnesota Medical Alumni Association for the erection of a suitable memorial for Dr. Millard's grave at Stillwater, is growing and the response on the part of the profession has been gratifying. Further contributions, however, are desired. Those who have as yet not responded to the request sent out a month ago are requested to send their contributions to Dr. Ralph Creighton, Medical Arts Building, Minneapolis.

Frederick Bass, member of the Engineering faculty at the University, was appointed to succeed Dr. S. Marx White of Minneapolis, and Dr. C. T. Oliver of Graceville to succeed Dr. C. F. Melby of Thief River Falls on the board. Arthur S. Milinowski of Stillwater, a sanitary engineer with offices in St. Paul, was also appointed to succeed L. P. Wolff, also an engineer in St. Paul. The appointment of the engineers was made upon recommendation of engineering societies.

The University Hospital and the Minneapolis General Hospital are each offering a six months' course of training in anesthesia to graduate nurses. One new student is entered at each hospital on the first of February, May, August, and November. Maintenance during the course is furnished.

The course is supervised by Dr. Ralph T. Knight and practical instruction furnished by the chief anesthetist and her assistants. The administration of nitrous oxide, ethylene, ether, and chloroform and the care of patients receiving spinal anesthesia are taught. After two weeks of observation and instruction the student administers anesthesia under supervision for three months.

Formal presentation of the medal offered by the Southern Minnesota Medical Association, for the best scientific exhibit at the meeting of the Minnesota State Medical Association, will take place at Faribault, Minnesota, on August 29, at the meeting of the Southern Minnesota Medical Association.

The award goes to Dr. William P. Herbst of Minneapolis for his exhibit on "A Study of the Motility of the Upper Urinary Tract Demonstrating the Diagnostic Features of Abnormal Motility Syndromes and the Indications of Drug Therapy and Renal Sympathectomy."

Honorable Mention was given to Dr. R. K. Ghormley, Dr. B. R. Kirklin and Dr. E. A. Brav of Rochester for their exhibit, "A Study of Surgical Specimens of the Knee Joint."

OBITUARY

HENRY L. WILLIAMS

1869–1931

Dr. Henry L. Williams, for twenty-two years coach of the University of Minnesota football teams, died June 14, 1931, at the age of sixty-two.

Born July 26, 1869, in Hartford, Connecticut, of English stock, Dr. Williams attended the public schools of Hartford and entered Yale in 1887. As an undergraduate he won his letters in football and track and the all-round track championship in his junior year. In his senior year he was captain of the track team.

After graduation he taught at a preparatory school ten miles from West Point, and besides coaching the preparatory teams went to West Point on Saturday afternoons to coach the Army teams.

Dr. Williams graduated from the medical school of Pennsylvania with honors in 1892 and spent three summers in post-graduate work in Germany.

From Philadelphia he came to Minneapolis in 1900 to become coach of the University track and football squads. In addition he practiced medicine and in 1912 became Assistant Professor of Gynecology, then resigned the following year to devote his spare time to private practice. For eight years "Doc" Williams coached the track teams but continuously acted as head coach of football until 1921, when a full-time coach was demanded.

Following the World War, Dr. Williams became executive in the Veterans Bureau headquarters in Minneapolis and later became District Medical Director for the United States Fidelity and Guaranty Company.

MORE MISBRANDED NOSTRUMS

The following products have been the subject of prosecution by the Food and Drug Administration of the U. S. Department of Agriculture, which enforces the Federal Food and Drugs Act: Antikamnia and Codeine Tablets (Antikamnia Remedy Co.), each containing 2.88 grains of acetanilid with caffeine, sodium bicarbonate and a small amount of codeine. A-No-Mor (A. G. Luebert), capsules containing 3 grains acetphenetidin, some acetylsalicylic acid and caffeine. Sargon (Sargon Laboratories), an alcohol-water solution of sugar, glycerin, extract of ox gall, a bitter drug, small amount of an iron compound, sodium citrate and caffeine. Gauvin's Headache Wafers (J. A. E. Gauvin), containing acetanilid and sodium bicarbonate. Hygem (Vita-Bac Corporation, Bloomfield Laboratories), consisting essentially of an emulsion of mineral oil, a small amount of casein-like material and water, flavored with peppermint oil and containing no viable acidophilus bacilli. Now (R. D. Coulson), consisting essentially of small amounts of menthol, camphor, oil of eucalyptus, licorice, alcohol, glycerin and water. Acquin (Clausen-Zoller Co.), containing acetphenetidin, acetylsalicylic acid and starch. (Jour. A. M. A., January 3, 1931, p. 57.)

« A PAGE FORUM OF THE COMMITTEE ON PUBLIC HEALTH EDUCATION »

"The Literary Digest Picks a Doctor"

Apparently there is still something seriously amiss with public knowledge of the functions of organized medical societies.

A certain C. Houston Goudiss of the New York *Forecast* has some excellent ideas about how to tell a quack when he sees one.

Neither he nor a *Literary Digest* commentator seems to know just how to go about picking an honest medical man.

The *Literary Digest* of May 30, 1931, was so much interested in Mr. Goudiss' ideas as published in the *Forecast* articles that it picked them up bodily, adding certain comments of its own and heading the combination with the caption, "HOW TO PICK A DOCTOR."

Suppose, they say, that you are alone and sick in a big city and there is not even a helpful hotel clerk downstairs to send up the hotel physician. What can you do to get a responsible properly qualified city substitute for the "old family doc" you left behind you?

How *do* you pick a doctor, in other words, according to the *Digest* and Mr. C. Houston Goudiss?

Well, here's how: you call the Young Women's Christian Association, or the Young Men's Christian Association, the Young Men's Hebrew Society, the local Rotary Club or the nearest hospital.

This last, says Mr. Houston Goudiss sagely, is your best bet because hospitals of any size, in any community, are required by law to maintain certain standards.

You tell by the following signs whether you have got hold of a quack or not: demands for money in advance; claims of a "special system" for all troubles; claims of some secret remedy or cure. All these should make you suspicious, says Mr. Goudiss. They are prima facie evidence of a faker.

The prima facie evidence of an honest regular practitioner is apparently much harder to describe. You must call this or that or the other lay organization to find out about him, or you must put in a claim for attention from some busy hospital.

These two may be taken to possess at least average intelligence and the average amount of information. What is the matter with the public relations of organized medicine, that neither had apparently ever heard of a county medical society?

They know, for instance, that a reputable practitioner must have got his degree from a reputable school; that he will be a member of reputable medical societies. But they know no simple way of checking up on either of these details.

Instead they counsel the sick, in need of more immediate attention, to call up the welfare organizations or a hospital to get their information second hand.

What about the general public if these men are so grossly uninformed?

County medical societies are enlarging and strengthening their organizations as never before. They are adding special committees for this type of public relation, other committees for that. They are more conscious and better equipped to take care of their public obligations than ever before.

Yet a large section of the public still knows nothing of the most fundamental and elementary service the county medical society has to offer—that of identifying and certifying honest physicians and protecting the public against quacks.

"Be suspicious," says the Goudiss article, in conclusion. "If you are sufficiently so, you will not entrust your most valuable possession to a faker. And if you insist upon having the facts you will go far toward the laudable goal of discouraging and eventually ridding our land of quacks."

The medical profession should certainly inform Mr. Goudiss just how it is prepared to assist his laudable campaign for discouraging quacks.

MISCELLANEOUS

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

ST. PAUL NATUROPATH FOUND NOT GUILTY ON ABORTION CHARGE

State of Minnesota *vs.* Hirst

William H. Hirst self-styled Naturopath with offices at 138 East Sixth Street, St. Paul, was found not guilty on an abortion charge by a jury after five hours' deliberation in the Court of the Honorable Howard Wheeler. The trial was the second one for the offense charged, the first trial ending in a disagreement after he jury had deliberated forty-three hours. The state alleged that the abortion took place on January 5, 1931. Following the defendant's arrest on that charge he entered pleas of guilty to two violations of the Basic Science Law, paying $500 fine on one charge and receiving a suspended sentence of one year in the Workhouse on the other. The Workhouse sentence was suspended on the condition that the defendant refrain from practicing healing in any manner in this State.

The present trial was conducted by Mr. John A. Pearson and Mr. James F. Lynch, assistants to Michael F. Kinkead, County Attorney. Mr. Brist, representing the State Board of Medical Examiners, reports that the case was very ably and conscientiously tried by Mr. Pearson and Mr. Lynch. The Honorable Howard Wheeler, Judge of the District Court, who presided at the trial, was very fair and impartial in the trial of the case.

MINNEAPOLIS QUACK PLEADS GUILTY TO VIOLATING THE BASIC SCIENCE LAW AND DISTRIBUTING PAMPHLETS ON RESTORATION OF "LOST MANHOOD AND LOST WOMANHOOD"

State of Minnesota vs. Ebeling (two cases)

On June 10, 1931, E. F. C. Ebeling, sixty-five years of age, self-styled doctor, entered two pleas of guilty to violating the Basic Science Law and the Statute against publishing and circulating circulars and pamphlets on the restoration of lost manhood and lost womanhood. The defendant had previously been given a warning by the State Board of Medical Examiners but failed to heed the same. His place of business was at 629 Third Avenue South, Minneapolis.

Following his arrest on May 26, defendant was unable to raise bail in the sum of $1,500, and he was confined in the county jail of Hennepin County for a period of fifteen days. At the end of that time he decided to plead guilty before the Honorable Judge Mathias Baldwin of the District Court, at which time he paid a one hundred dollar fine for maintaining an office in violation of the Basic Science Law, and was given a one year sentence in the Minneapolis Workhouse, which sentence was suspended for a period of two years on condition that he refrain from violating the Medical Laws of this State.

Mr. Brist, representing the State Board of Medical Examiners, reports very good coöperation from Mr. Ed. J. Goff, recently elected County Attorney of Hennepin County, and his assistants, Mr. Neilson and Mr. Poirier. Judge Clyde R. White of the Municipal Court, who presided at the preliminary hearing of the defendant, and Judge Mathias Baldwin, before whom the case was disposed of in the District Court, were very fair in their attitude towards these two cases.

This is the first time since the passage of the Basic Science Law that the Medical Board has instituted proceedings under the Statute on advertising of a treatment for the restoration of lost manhood and lost womanhood. The Statute in question is set out below for the convenience of the members of the medical profession. The Medical Board will appreciate receiving any literature that comes to the attention of the members of the profession in violation of this law.

Sections 10191, 10192 and 10193, Mason's Minnesota Statutes for 1927.

10191. CERTAIN MEDICAL ADVERTISEMENTS—PENALTY—Any person who shall advertise, in his own name or the name of another person, firm or pretended firm, association, corporation or pretended corporation, in any newspaper, pamphlet, circular, or other written or printed paper, or the owner, publisher, or manager of any newspaper or periodical who shall permit to be inserted or published in any newspaper or periodical owned or controlled by him, the treatment or curing of venereal diseases, the restoration of "lost manhood" or "lost vitality," or shall advertise in any manner that he is a specialist in diseases of the sexual organs, or diseases caused by sexual weakness, self-abuse, or excessive sexual indulgence, or in any disease of like causes, or who shall advertise in any manner any medicine, drug compound, appliance or any means whatever whereby it is claimed that sexual diseases of men and women may be cured or relieved, or miscarriage or abortion produced, shall be guilty of a gross misdemeanor and shall be punished by a fine of not less than fifty dollars nor more than five hundred dollars or by imprisonment in the county jail for not more than six months. ('09 c. 162 Sec. 1) (8709)

10192. PUBLICATION, ETC.—PENALTY—Any person publishing, distributing, or causing to be distributed or circulated, any of the advertising matter herein above prohibited shall be guilty of a misdemeanor and punished as prescribed in section 1 of this act. ('09 c. 162 Sec. 2) (8710)

10193. EVIDENCE—The production of any advertisement or advertising matter published or distributed contrary to the provisions of this act shall be of itself prima facie evidence of the guilt of the person or persons advertising to cure any such disease herein above mentioned, or of the publishers who publish any matter such as is herein prohibited. ('09 c. 162 Sec. 3) (8711)

NEGRO QUACK SENTENCED ON TWO CHARGES

State of Minnesota *vs.* Robert McGraw (2 cases)

Robert McGraw, sixty-five years of age, a negro quack who formerly practiced at Hewitt and Villard, Minnesota, was arrested on Monday, June 8, at Winsted, Minnesota, charged with violating the Basic Science Law. McGraw was previously tried on two occasions before Judge Flaherty at Glenwood for violating the medical laws of this state, but at each trial Judge Flaherty dismissed the case when the State rested. The State Board of Medical Examiners was informed that McGraw had located in McLeod County and he accordingly was arrested by complaint filed by Mr. Brist, representing the Board. On Thursday, June 11, a second complaint was filed against McGraw because of Mc-

Graw's attempting to cure a case of Hodgkin's disease This case had been previously diagnosed by Dr. Chester J. Olson of Belle Plaine, Minnesota, as Hodgkin's disease with the usual prognosis. This did not prevent McGraw, however, from agreeing to cure the ailment within three months.

Upon the recommendation of Wm. O. McNelly, County Attorney, of McLeod County, Judge Kohler of the Municipal Court at Glencoe set McGraw's bail at $2,000. McGraw was unable to raise this bail and he was accordingly confined in the county jail at McLeod County. The next term of Court in Glencoe is in November and this may have been a factor in McGraw's deciding to plead guilty.

On Friday, June 12, McGraw entered pleas of guilty to both charges before the Hon. C. M. Tifft. Judge Tifft fined McGraw $225 and costs of $13.25 on the first charge, which fine was paid. Defendant seemed to be short of ready cash, for he sold his automobile in order to pay the fine. On the second charge Judge Tifft sentenced McGraw to one year in the county jail of McLeod County, and suspended the sentence on the following conditions:

1. McGraw is to return immediately to his native state of Illinois.
2. He is to refrain from the practice of healing in the State of Minnesota.
3. He is not to return to this state except that he is given forty-eight hours to come in and get his ten-year-old boy who is ill with the measles. When the boy is well McGraw is to be notified and he is to report to the Sheriff of McLeod County when he comes in to get the boy and when he leaves, which period of time is not to exceed forty-eight hours.
4. The Court expressly reserved the right to revoke the suspension of the sentence at any time the Court sees fit, either for cause or without cause.

Judge Tifft warned the defendant against attempting to practice in his home state of Illinois or anywhere else unless he was licensed.

McGraw said that he had spent $2,500 in the past three years fighting these cases and for that reason he was not hiring a lawyer for this case.

This brings to a close three years of work on the part of the State Board of Medical Examiners to eliminate one of the most vicious quacks in the State of Minnesota. The defendant is an unkempt, illiterate quack whose riddance is a blessing not only to the people of this State but to the medical profession as well. The medical profession owes a debt of gratitude to the men who brought about the successful termination of this matter and particularly Judge Kohler of the Municipal Court at Glencoe, John Luiten, Clerk of the District Court, Wm. O. McNelly, County Attorney of McLeod County; Sheriff Alfred T. Beihoffer of McLeod County and the Honorable C. M. Tifft, Judge of the District Court, Glencoe, Minn. The coöperation displayed by Sheriff Beihoffer and County Attorney McNelly and the conditions imposed by Judge Tifft in suspending the jail sentence, clearly shows that there authorities will not tolerate any such quackery in their district.

NEW AND NON-OFFICIAL REMEDIES

The Council on Pharmacy and Chemistry has accepted the following:

Hixson Laboratories, Inc.
  Rabies Vaccine (Hixson)
Lederle Laboratories, Inc.
  Concentrated Pollen Antigen (Lederle) Ragweed
  Combined Diphtheria Toxin for Schick Test in Peptone Solution
Eli Lilly & Co.
  Diphtheria Toxoid-Lilly
  Syrup No. 112 Ephedrine Hydrochloride
Chas. Pfizer & Co.
  Calcium Gluconate-Pfizer
Spicer & Co.
  Quiniobine
  Quiniobine Ampules, 2 c.c.
E. R. Squibb & Sons
  Grasses Combined Pollen Allergen Solution-Squibb
  Cottonwood Pollen Allergen Solution-Squibb

The following articles have been exempted and included with the List of Exempted Medicinal Articles (New and Non-official Remedies, 1930, p. 477):

Hixson Laboratories, Inc.
  Diphtheria Antitoxin
  Tetanus Antitoxin

TRUTH ABOUT MEDICINES

Mead's Powdered Brewer's Yeast.—Dried brewer's yeast harvested under aseptic conditions; it assays approximately 13 vitamin B_1 units per gram and approximately 1 vitamin B_2 units per gram. The product is proposed for prophylaxis and treatment of conditions arising from deficiency of the vitamin B complex in the diet. It is also proposed as a means of stimulating the appetite and growth and for a beneficial effect in lactation. Mead Johnson & Co., Evansville, Ind. (Jour. A. M. A., May 2, 1931, p. 1477).

Diphtheria Toxoid.—A diphtheria toxoid (New and Non-official Remedies, 1930, p. 364) prepared from diphtheria toxin by treatment with formaldehyde. It is marketed in packages of one immunization treatment and in packages of fifteen immunization treatments. Eli Lilly & Co., Indianapolis.

Ampules Solution of Nupercaine-Ciba, 25 c.c.—A 1:1,000 solution of nupercaine-Ciba (Jour. A. M. A., March 21, 1931, p. 946). Ciba Co., Inc., New York.

Schieffelin Psyllium Seed.—A brand of psyllium seed-N.N.R. (New and Non-official Remedies, 1930, p. 311). Schieffelin & Co., New York. (Jour. A. M. A., May 16, 1931, p. 1694.)

Diphtheria Toxin for Schick Test in Peptone Solution.—A diphtheria toxin (New and Non-official Remedies, 1930, p. 380) made by growing diphtheria bacilli in broth, aging and diluting with peptone solution according to J. E. Bunney. The product is ready for use. It is marketed in packages of one syringe containing diluted diphtheria toxin sufficient for one est and in packages of one vial containing sufficient for en tests. As a means of control, diphtheria toxin heated to 75 C. and diluted with peptone solution is supplied. Lederle Laboratories, Inc., Pearl River, N. Y.

Pollen Allergen Solutions-Squibb.—The following pollen allergen solutions-Squibb (New and Non-official Remedies, 1930, p. 27; Jour. A. M. A., December 20, 1930, p. 1913), marketed in 5 c.c. vials, has been accepted: Cottonwood Pollen Allergen Solutions-Squibb. The following pollen allergen solutions-Squibb (New and Non-official Remedies, 1930, p. 27; Jour. A. M. A., December 20, 1930, p. 1913), marketed in 5 c.c. vials, in treatment set packages, A, B, C and D, and in three vial treatment packages, has been accepted: Grasses Combined Pollen Allergen Solutions-Squibb (Bermuda Grass, June Grass, Orchard Grass, Red Top, and Timothy, in equal parts). E. R. Squibb & Sons, New York. (Jour. A. M. A., May 30, 1931, p. 1872.)

FOODS

The following products have been accepted by the Committee on Foods of the Council on Pharmacy and Chemistry of the American Medical Association for inclusion in Accepted Foods:

Zed Biscuits (Zed Corporation, San Francisco, Calif.).—Twice baked biscuits, leavened with baking powder, containing cracked whole wheat, whole wheat flour, rye meal, oat meal, wheat bran, bread flour, coconut oil, buttermilk (cultured), caramelized sugar, brown sugar and a mixture of orange, pineapple, grape and apple juices. Zed biscuits are claimed to be wholesome, nutritious, regulative and delicious.

Merrell-Soule Powdered Cultured Skimmed Lactic Acid Milk (Akrelac) (Merrell-Soule Co., Inc., New York).—This is a powdered artificial buttermilk, soured with pure culture of lactic acid organisms *(Streptococcus lactis)*. The use of the product is proposed by the manufacturer to rectify digestive disturbances under artificial feeding, for acute intestinal disturbances, prolonged malnutrition, and complemental feeding.

Wheatena (The Delicious Wheat Cereal) (The Wheatena Corporation, Wheatenaville, Rahway, N. J.).—A toasted granular wheat cereal composed of the embryo, essentially all of the endosperm and the major portion of the bran of red winter wheat. Wheatena is claimed to be a quick cooking wheat breakfast cereal with an individual toasted flavor requiring from two to three minutes for preparation. (Jour. A. M. A., May 2, 1931, p. 1478.)

Olde-Tyme Breads (Family, Round, Hearth and Pullman) (The City Bakery, Bellefonte, Pa.).—White bread loaves in wax-paper or "glassine" wrappers.

Sliced Purity Bread (Purity Baking Co., Ottawa, Ill.).—A sliced white bread made by the sponge dough method.

Merrell-Soule Powdered Protein Milk (Boilable) (The Merrell-Soule Co., Inc., New York).—A powdered food made from milk; higher in protein and mineral salts, lower in lactose than dry whole milk. It is only slightly acid. The preparation is proposed for use in infant feeding.

Amaizo Golden Syrup (Corn Syrup and Refiners' Syrup) (American Maize-Products Co., New York).—A blend of corn syrup and refiners' syrup flavored with vanilla extract. (Jour. A. M. A., May 16, 1931, p. 1695.)

Mead's Powdered Lactic Acid Milk Noncurdling No. 1 with Dextri-Maltose (Mead Johnson & Co., Evansville, Ind.).—A powdered, spray-dried homogenized milk containing added lactic acid, maltose and dextrin. It is claimed that the mixture with water may be boiled without curdling or change of color or taste. It is proposed for use in infant feeding.

Libby's Tomato Juice (Libby, McNeill & Libby, Chicago).—A pasteurized tomato juice, seasoned with salt. It is claimed that the method of preparation tends to retain the vitamins of the original fruit. It is claimed that the product is a food which stimulates the appetite and that, like orange juice, it is a protective food against scurvy.

Self Rising Washington Flour (Wilkins-Rogers Milling Co., Washington, D. C.).—A mixture of wheat flour with baking powder leavening and seasoning—calcium acid phosphate, sodium bicarbonate and salt. The flour is claimed to be adapted to biscuit, pastry and cake baking. (Jour. A. M. A., May 23, 1931, p. 1780.)

Jerry's Kew-Bee Bread (Jerry's Bakery Co., Terre Haute, Ind.)—A white bread made by the sponge dough method.

Page Evaporated Milk (Sterilized, Unsweetened) (The Page Milk Co., Merrill, Wis.).—An unsweetened evaporated milk. A mixture of one part water and one part of this product corresponds to the legal standard for whole milk.

Vermont Maid Bread (Vermont Baking Co., White River Junction, Vt.).—A white bread made by the sponge dough method.

Staley's Golden Table Syrup (A. E. Staley Manufacturing Co., Decatur, Ill.).—A table syrup; a corn syrup base (glucose) flavored with choice refiners' syrup.

Staley's Crystal White Syrup (A Savory Blend of Pure Corn Syrup, Granulated Sugar Syrup and Vanilla) (A. E. Staley Manufacturing Co., Decatur, Ill.).—It is a mixture of corn syrup base (glucose) and sucrose flavored with vanilla extract. (Jour. A. M. A., May 30, 1931, p. 1872.)

Velveeta (Kraft-Phenix Cheese Corporation, Chicago).—A delicious cheese food. Kraft Process American Cheese with added milk sugar, milk minerals and water. A cheddar cheese admixed with cream (or butter and skim milk powder), milk-whey powder and salt. The approximate composition is: moisture, 44 per cent; ash, 6 per cent; fat, 25.5 per cent; protein, 18 per cent; lactose, 6.3 per cent; calcium, 0.53 per cent; phosphorus, 0.71 per cent; 75 mg. of Velveeta is equivalent to 10 mg. of butter in Vitamin A potency. Velveeta is claimed by the manufacturer to be richer in milk minerals and lactose than the usual cheeses not containing the milk-whey. (Jour. A. M. A., March 21, 1931, p. 947.)

CONSULTATION BUREAU

Wm. A. O'Brien, M.D., *Director*
Minnesota State Medical Association
11 West Summit Avenue
Saint Paul, Minnesota

1. *Question.*—Five weeks ago, a woman, 28 years old, married six months, never pregnant, woke up at 5:00 A. M. with a severe pain in the right hip region. It was exquisitely tender. Pressure along the course of the sciatic nerve was very painful. Deep pressure over the long bone was not so distressing. There was no elevation of temperature until one week later, when her temperature rose to 100 for a day or two and then went to normal; stayed normal for four days and since then has been of the intermittent type. The highest point was 101.5 and the lowest 98. The pulse has been around 80 for two weeks. During the last two weeks it has become more rapid and for the past five days has been rather constant at 120 beats per minute.

Physical examination has been negative all along. No cardiac findings. Shifting tenderness over the right leg is getting general. Pain extends to the shoulders, the back and sometimes just from the knee to the ankle.

Last week she had four definite chills in five days. The temperature did not go up above 101.5 but there was an increase in the pain along with the chill. None of the joints has ever showed any signs of redness or swelling.

Two days ago, she began to have dysuria with frequency, passing three or four ounces every half hour. The urine has been negative daily as far as albumin, sugar, or any other abnormal constituent is concerned. The acidity has been low.

X-ray examination of the bones is negative. Repeated pelvic examinations have yielded no abnormal findings. The white blood count has varied from 8,150 to 14,000. May 15, the hemoglobin report was 60 per cent (Tallqvist), red blood count 4,690,000, white blood count 8,150, and the differential-neutrophils 66 per cent, small lymphocytes 7 per cent, large lymphocytes 26 per cent, transitional cell 1, and no eosinophils nor basophils seen. The large lymphocytes look rather immature to me.

At times the pain was so severe that it required morphine or pantopon of fairly good sized doses. This at times has failed to control it and does not permit very much sleep. The ordinary analgesics have not been of any particular value.

There is no glandular enlargement, even the tonsils are very small. Have noted two small nodules, subcutaneous in location, in the right lower abdominal region. One appeared about ten days ago and the other four days ago. They are about the size of a large pea and are moderately tender to touch.

I would greatly appreciate your opinion in this matter.

Answer.—It is not likely that the suggestive immaturity of the lymphocytes is significant in this case. The differential count showing the usual excess of neutrophils is against any diagnosis of leukemia at this stage. We sometimes see this type of cell in infections but are unable to use it in any way to make a diagnosis.

As far as the subcutaneous nodules are concerned, I would advise you to do a biopsy and have a microscopic section done. This will clear up any relationship to the case.

The diagnostic possibilities are: Arthritis, bone tumor, or osteomyelitis or periostitis. The absence of positive X-ray bone findings is not against any bone or joint diagnosis and I would suggest that you repeat this part of the examination. We frequently see cases early in their course which do not show any findings either of tumor or inflammation. Later plates would show the process very clearly.

The commonest type of bone tumor, associated with severe pain, fever and other signs of infection is Ewing's tumor, which is an endothelioma and involves any part of the skeleton, either in one or several places. An interesting complication frequently seen is simultaneous involvement of the lymph nodes and visceral metastasis.

Pelvic infections, as a general rule, do not cause a severe type of hip pain. The bladder symptoms and location of the pain are suggestive of psoas abscess. Could it be possible that there is anything in the lumbar vertebra? Metastatic bone tumors cannot be ruled out until a careful research has been made for the primary. It is possible that the subcutaneous nodules, that you mention, might be helpful in clearing up this point.

We doubt that it is in any way associated with a leukemic process. Hodgkin's may involve the bone and cause severe pain. Deep visceral Hodgkin's may be present without enlargement of the nodes. Again, a biopsy of the nodules would be helpful.

In our experience, arthritis of the infective type (rheumatic) seldom causes severe pain over such a long period of time as you have noted in your case. Tumors, primary or metastatic, suppurative arthritis, osteomyelitis or periostitis and Hodgkin's disease are more likely.

2. *Question.*—Occasionally I examine the secretions from the prostate gland under the microscope. Usually I find many white cells. Is this normal? Do one-third of all males have prostatic infection?

Answer.—A few white cells is the usual finding. An increase means inflammation. You are right in the statement that about one-third of all males after 30 years of age have prostatic infection, but very few give any trouble.

REPORTS AND ANNOUNCEMENTS OF SOCIETIES

MEDICAL BROADCAST FOR THE MONTH

The Minnesota State Medical Association Morning Health Service.

The Minnesota State Medical Association broadcasts weekly at 10:15 o'clock every Wednesday morning over Station WCCO, Minneapolis and St. Paul (810 kilocycles or 370.2 meters).

Speaker: William A. O'Brien, M.D., Associate Professor of Pathology and Preventive Medicine, Medical School, University of Minnesota.

The program for the month of July will be as follows:

July 1—Safety First for the Fourth.
July 8—Cause of Albumin in Urine.
July 15—Type I Pneumonia.
July 22—Aims of Education.
July 30—Newer Knowledge of Cancer.

THE AMERICAN COLLEGE OF PHYSICIANS

The American College of Physicians will hold its Sixteenth Annual Clinical Session at San Francisco with headquarters at the Palace Hotel, April 4 to 8, 1932. Following the Clinical Session, a large percentage of the attendants will proceed to Los Angeles, where a program principally of entertainment will be furnished April 9, 10 and 11.

Announcement of the dates is made particularly with a view not only of apprising physicians generally of the meeting, but also to prevent conflicting dates with other societies that are now arranging their 1932 meetings.

Dr. S. Marx White, of Minneapolis, is President of the American College of Physicians, and will arrange the Program of General Sessions. Dr. William J. Kerr, Professor of Medicine at the University of California Medical School, San Francisco, is General Chairman of local arrangements, and will be in charge of the Program of Clinics. Dr. Francis M. Pottenger, of Monrovia, is President-Elect of the College, and will be in charge of the arrangements at Los Angeles. Mr. E. R. Loveland, Executive Secretary, 133-135 S. 36th Street, Philadelphia, Pa., is in charge of general and business arrangements, and may be addressed concerning any feature of the forthcoming session.

NORTHWESTERN PEDIATRIC SOCIETY AND STAFF OF CHILDREN'S HOSPITAL—JOINT MEETING

A joint meeting of the Northwestern Pediatric Society and the Staff of the Children's Hospital was held at the Children's Hospital, Saint Paul, May 20, 1931. Thirty-eight members were present.

The meeting was called to order by the President, Dr. Samuel Amberg, at 8:15 p. m. Dr. Amberg suggested that, owing to the length of the program, we dispense with the reading of the minutes of last meeting.

It was moved by Dr. Thomas Myers, seconded by Dr. W. Ray Shannon, that five meetings be held this year: the spring meeting at Saint Paul, the summer meeting at Rochester, the fall meeting in Duluth, the winter meeting at Minneapolis, and the annual meeting at the Town and Country Club, Saint Paul. At these meetings members from other towns have the privilege of presenting papers.

The following clinical program was then presented by the Staff of the Children's Hospital:

1. Spontaneous subarachnoid hemorrhage..................Dr. Critchfield
   Discussion ....Dr. Andrews
2. Chronic suppurative parotitis..........Dr. Birnberg
3. Liver abscess..........Dr. Colby
   Discussion.........Drs. Ikeda, McQuarrie and Shannon
4. Recent progress in child psychiatry....Dr. Lippman
   Discussion ....Dr. Amberg
5. Pediatrics in Ancient Egypt..........Dr. Rosenthal
   Discussion ....Dr. McQuarrie
6. Pulmonary tuberculosis..........Dr. Myers
7. Unusual case of diabetes..........Dr. Ramsey
   Discussion....Drs. Shannon, Andrews and McQuarrie

Alexander Stewart,
Secretary-Treasurer.

REDWOOD-BROWN COUNTY SOCIETY

On Tuesday, May 19, 1931, the Redwood-Brown County Medical Society held its annual meeting at New Ulm. Dinner was served to the doctors and their wives at 6:30 p. m. in the parlors of the Methodist Church, fifty-two being present.

After the dinner all repaired to the home of Dr. and Mrs. Geo. F. Reineke, where the women organized a local chapter of the State Medical Auxiliary, while the doctors held their scientific meeting.

Dr. F. A. Willius, of the Mayo Clinic, delivered an able lecture on "Heart Disease, including the discussion of sudden death." This lecture was illustrated by slides thrown upon the screen by Dr. Monte Piper, also of the Mayo Clinic.

The following officers were elected for the ensuing year: Dr. F. H. Dubbe, New Ulm, president; Dr. A. P. Goblirsch, Sleepy Eye, vice-president; Dr. Wm. A. Meierding, New Ulm (re-elected), secretary-treasurer; Dr. Geo. B. Weiser, New Ulm, state delegate; Dr. J. P. Vogel, New Ulm, alternate; Dr. Theo. Hammermeister, New Ulm (re-elected), censor.

The Chairman appointed the following committees: Publicity, as well as Public Health—Dr. Geo. B. Weiser, New Ulm; Dr. Wm. McLane, Sleepy Eye, and Dr. J. C. Rothenburg, Springfield.

Maternal and Infant Hygiene—Dr. Geo. B. Weiser, New Ulm, and Dr. E. Jamieson, Walnut Grove.

Public Policy and Legislation—Dr. J. C. Rothenburg, Springfield, and Dr. Theo. Hammermeister, New Ulm.

It was decided to have the president appoint a committee of three who were to arrange for more frequent meetings during the year and to arrange for suitable programs. These meetings may be held in various cities and towns providing the local physicians arrange for a suitable meeting place.

A resolution was passed that our society go on record as disapproving of free medical and surgical services being given ex-service men for disabilities not incurred in the service, as this practice is a big step towards socialized medicine.

WM. A. MEIERDING, Secretary.

SOUTHERN MINNESOTA MEDICAL ASSOCIATION

The annual meeting of the Southern Minnesota Medical Association will be held at Faribault, August 24, 1931, at the Shattuck School. The program this year will be similar to the one given last year in that clinical demonstrations and clinics will be held in the morning with a formal program in the afternoon and a banquet with prominent speakers in the evening. The completed program will be published in the August number of MINNESOTA MEDICINE.

SOUTHWESTERN MINNESOTA MEDICAL SOCIETY

The semi-annual meeting of the Southwestern Minnesota Society was held at Luverne, Minnesota, May 11, 1931. Thirty-three doctors were present. The following program was given:

"State Medical Society"
Dr. L. L. Sogge, Windom, Minn.
"Spinal Anesthesia"
Dr. Sydney Watson, Worthington, Minn.
"Medical Economics"
Dr. C. L. Sherman, Luverne, Minn.
"Report on State Medical Meeting"
Dr. E. W. Arnold, Adrian, Minn.
"The Relation of the Medical Profession to State Senate"
Sen. Frank J. Snell, Adrain, Minn.
"The Attitude of the Medical Profession to Workman's Compensation"
Sen. J. V. Weber, Slayton, Minn.

Rep. John Connell, Luverne, Minn., was also present and gave a very interesting talk.

E. G. MCKEOWN, M.D.,
Secretary.

WABASHA COUNTY SOCIETY

The sixty-third annual meeting of the Wabasha County Medical Society will be held at Lake City, Minnesota, Thursday, July 9, 1931.

Following the business session in the morning dinner will be served at the Hotel Lyon, where members will be guests of the Lake City members and affiliated dentists.

"Minnesota Wild Life in Motion Pictures" will be presented in three reels with a talk by Professor Thomas S. Roberts, Director of the Zoölogical Museum, University of Minnesota.

The scientific program in the afternoon will be as follows:

President's Address—"Further Report on Undulant Fever, with Three Additional Cases." Dr. E. C. Bayley, Lake City
"Tuberculous Salpingitis"—Dr. Alfred Belitz, Pepin, Wisconsin
"Medical Policies Discussed at the 1931 County Secretaries' Meeting"—Dr. W. F. Wilson, Lake City

WASHINGTON COUNTY SOCIETY

The regular meeting of the Washington County Medical Society, which was held Tuesday, May 12, was, in some respects, our most successful meeting. The attendance was good. Dr. J. F. Borg of St. Paul, our guest speaker, gave a fine and comprehensive talk on "Arterio- and Arteriolo-sclerosis." From the number of questions asked, there is no doubt that much interest was taken in this important subject.

The Society was quite interested in the proceedings of the Council and the House of Delegates. It was especially interested in the resolution of the Hennepin County Surgical Society, and the report of Dr. O. E. Locken of Crookston.

During the short existence of our County Committee on Public Health Relations decided results have been produced. Contact with P. T. A. is becoming more and more satisfactory; the 4-H Club is fine and owes its success to the enthusiastic support given us by Mr. A. Sjewall. Through him our Committee has been able to make arrangements for a Health Booth at the coming County Fair, with doctors and a nurse in attendance to explain preventive measures as known and practiced today. Charts and posters will also be used with attractive decorations to draw the attention of Fair visitors. We owe Mrs. P. F. Murphy, Secretary of the Washington County Public Health Association, who is our staunch supporter, a great deal for her valuable help in making these contacts.

As far as practical, we are going to apply the tuberculin test (Mantoux) to school children in the eighth grade and first year High School, some time this summer. We are also trying to make arrangements for the examination of pre-school children and toxin-antitoxin tests. This seems to me to be a pretty fair beginning.

E. SYDNEY BOLEYN, M.D., *Secretary.*

OLD TUBERCULIN IN THE TREATMENT OF TUBERCULOSIS

Koch reported tuberculin to the profession in 1890, and it was hailed as a specific remedy; unfortunately, it was administered in a somewhat reckless way by inexperienced clinicians, and the disadvantages soon resulted in widespread condemnation. Tuberculin is not a selective curative remedy in the treatment of tuberculosis. It is not a specific. It should not be used by general practitioners in routine office practice, but by specialists in the sanatorium or home where there is careful clinical supervision of the patients. (Jour. A. M. A., May 16, 1931, p. 1720.)

WOMEN'S AUXILIARY

Minnesota State Medical Association

President—Mrs. S. S. Hesselgrave, St. Paul
Chairman Press and Publicity—Mrs. E. A. Meyerding, St. Paul
Editor—Mrs. A. A. Passer, Olivia

PRESIDENTS OF THE WOMEN'S AUXILIARY TO THE COUNTY MEDICAL SOCIETIES, 1931

Blue Earth County	Mrs. A. E. Sohmer, Mankato
Camp Release	Mrs. J. S. Kilbride, Canby
Hennepin County	Mrs. Martin Nordland, Robbinsdale
McLeod County	Mrs. Thos. J. Trutna, Silver Lake
Meeker County	Mrs. A. W. Robertson, Litchfield
Mower County	Mrs. A. W. Allen, Austin
Nicollet-Le Sueur	Mrs. Joseph O. McKeon, Montgomery
Olmsted County	Mrs. M. S. Henderson, Rochester
Park Region	Mrs. C. O. Estrem, Fergus Falls
Ramsey County	Mrs. W. H. Hengstler, 1120 Lincoln Ave., St. Paul
Red River Valley	Mrs. B. C. Bernard, Thief River Falls
Redwood-Brown County	Mrs. Wm. A. Meierding, New Ulm
Rice County	Mrs. M. L. Mayland, Faribault
Scott-Carver County	Mrs. B. H. Simons, Chaska
Stearns-Benton	Mrs. Werner Hemstead, St. Cloud
Steele County	Mrs. A. B. Hart, Sr., Owatonna
St. Louis County	Mrs. F. N. Knapp, 327 Kenilworth Ave., Duluth
Southwestern Minn.	Mrs. L. Sogge, Windom
West Central	Mrs. Chas. Bolsta, Ortonville
Washington County	Mrs. J. W. Stuhr, Stilwater
Wright County	Mrs. John Catlin, Buffalo

The Women's Auxiliary has gained ten new auxiliaries during the past year under the direction of the organization chairman, Mrs. James Blake. Minnesota now has 23 auxiliariés, comprising 54 counties; 267 new members this year; 937 paid members, state and national; 78 paid in state; 1,024 listed as members (46 delin-uent). Lyon-Lincoln Medical Society has authorized n Auxiliary to be organized at a meeting called for une 29 at Tracy.

CAMP RELEASE AUXILIARY

Officers of the Camp Release Auxiliary met in executive session at Granite Falls, May 26, after a picnic unch. Mrs. J. S. Kilbride, Canby, president of the uxiliary, presided. She was assisted by the members f her board: Mrs. C. M. Johnson, Dawson, vice presi-ent; Mrs. George H. Mesker, Olivia, second vice presi-ent; Mrs. R. C. Adams, Bird Island, secretary; Mrs. . G. Smith, Montevideo, treasurer. It was voted to ave a joint picnic with Camp Release Medical Society t Green Lake in June. The following committees were ppointed: Membership—Mrs. R. C. Adams, Mrs. H. ohnson, Mrs. R. Billings; Entertainment—Mrs. George Mesker, Mrs. L. G. Smith, Mrs. L. J. Holmberg; Pub-city—Mrs. A. A. Passer; Legislative—Dr. Kathleen ordan; Public Health—Mrs. M. A. Burns; Nominating—Mrs. A. G. Sanderson; Mrs. M. S. Nelson, Mrs. Dordal.

RAMSEY COUNTY AUXILIARY

Ramsey County Auxiliary held its annual picnic and nnual business meeting and election of officers on Mon-ay, May 25, at the summer home of Mrs. Henry N. lein, Turtle Lake. Reports of officers and chairmen were given, showing an active year. Mrs. Hesselgrave, state president, was guest of honor and thanked the members of her own Auxiliary for their splendid cooperation with the state and national auxiliaries throughout the past year. The election resulted as follows: Mrs. W. H. Hengstler, president; Mrs. Karl Dedolph, vice president; Mrs. O. W. Holcomb, second vice president; Mrs. Harry Ghent, recording secretary; Mrs. C. C. Bell, corresponding secretary; Mrs. Donald Bacon, treasurer; Mrs. E. M. Hammes, auditor.

REDWOOD-BROWN AUXILIARY

At a meeting held in New Ulm, May 19, the Redwood-Brown Auxiliary was organized and the following officers were elected: Mrs. Wm. A. Meierding, New Ulm, president; Mrs. A. P. Goblirsch, Sleepy Eye, vice president; Mrs. Albert Fritsche, New Ulm, secretary-treasurer. The members of the new auxiliary and the doctors held a joint banquet and it was observed that the meeting was unusually well attended and due credit was given to the auxiliary. Fifty-four were present at the banquet.

RICE COUNTY AUXILIARY

The Women's Auxiliary to the Rice County Medical Society met on May 13 at the home of Mrs. C. A. Traeger of Faribault. Mrs. P. F. Meyers, chairman of the nominating committee, presented names for election of officers. The following were elected for the coming year: Mrs. M. L. Mayland, president; Mrs. Warren Wilson, vice president; Mrs. A. L. Haynes, secretary; Mrs. Orin Thorson, treasurer. A report of the state meeting held in Minneapolis in May was given by Mrs. A. M. Hanson. A layette was furnished for the Northfield hospital. Refreshments were served by the hostess and the meeting adjourned until October. Mrs. C. J. Plonske and Mrs. M. L. Mayland will attend the National Auxiliary meeting in Philadelphia in June.

SOUTHWESTERN MEDICAL AUXILIARY

A Women's Auxiliary to the Southwestern Medical Society was organized on May 11 in Luverne. The meeting was called for 8 p. m. at the home of Mrs. C. L. Sherman. Mrs. S. S. Hesselgrave, St. Paul, and Mrs. James Blake, Hopkins, were present and aided in perfecting the organization of this new group. The following officers were elected: President, Mrs. L. Sogge, Windom; Vice President, Mrs. E. W. Arnold, Luverne; Secretary-Treasurer, Mrs. E. A. Kilbride, Worthington.

STEARNS-BENTON AUXILIARY

The annual meeting of the Auxiliary was held in the Art Shop tea room on Tuesday, May 12, in St. Cloud. One o'clock luncheon was served to the sixteen members present. Annual reports of the officers were read and accepted. Mrs. J. D. Kohler of St. Joseph was elected second vice president; Mrs. J. J. Gelz, corresponding secretary; and Mrs. Jennie Havorka, treasurer. On Saturday evening, May 16, the Stearns-Benton Medical Society entertained the members and their wives of Upper Mississippi and Wright county societies in the community room of the Court House in St. Cloud. The moving pictures of Surgical Technic which had been presented at the state convention in Minneapolis in May were shown. The Auxiliary served lunch after the program. Tuesday, May 26, Mrs. J. C. Buscher of St. Cloud entertained the Auxiliary Bridge club at her home. Honors were won by Mrs. H. B. Clark and Mrs. J. E. Dwyer.

STEELE COUNTY AUXILIARY

The Steele County Medical Society held a special meeting and banquet at the Owatonna Hotel. Dr. L. R. Critchfield of St. Paul was the guest of honor. Other guests included Mrs. Critchfield, Miss Agnes Melbostad, Miss Emma Leach, and the wives of the members of the Steele County Society. At the close of the banquet, the ladies adjourned to the parlors, where the Women's Auxiliary of the Steele County Medical Society was formed with the following officers elected: Mrs. A. B. Hart, Sr., president; Mrs. A. B. Stewart, vice president; Mrs. E. W. Senn, secretary; Mrs. L. V. Berghs, treasurer. This auxiliary plans to affiliate with the state and national auxiliaries at a meeting June 19. For the present meetings will be held on the third Friday of each month at the Owatonna City Hospital.

WASHINGTON COUNTY AUXILIARY

The annual meeting of the auxiliary was held at the home of Mrs. F. G. Landeen on Tuesday afternoon, June 2. Miss Christine Strom, superintendent of Lakeview Memorial Hospital, gave a talk on "A Résumé of a Student in Our School of Nursing." The Women's Auxiliary and the Washington County Medical Society will hold a joint picnic July 9, at the home of Dr. and Mrs. Henry Van Meier on Lake St. Croix. New officers for the ensuing year were elected as follows: Mrs. Wilfred Hewson, president; Mrs. E. V. Strand, vice president; Mrs. R. J. Josewski, secretary and treasurer.

SCIENCE AND THE ADVERTISER

Printers' Ink, a journal for advertisers, is anxious to establish a "Forget Scientists Week": "Perhaps you have been so foolish as to think that scientists worked at the business of science. Not so. They test cigarettes, tell frightened mothers about breakfast foods, warn young men against the dangers of something that usually ends with -osis. Now and then to be sure they make an epoch-making discovery which will bring about an astounding revolution in the manufacture of nine-count, full-fashioned galoshes. In short, they are scientists of the advertising pages." *Printers' Ink* recognizes the dismay that has been aroused in scientists generally by the exploitation of pseudoscience in advertising. It ridicules those who are now preparing copy for advertisements in modern periodicals because they are so utterly lacking in originality. Advertising in the periodicals of the United States has gone to lengths that have opened it to ridicule and censure. (Jour. A. M. A., May 23, 1931, p. 1799.)

PROCEEDINGS OF THE MINNEAPOLIS SURGICAL SOCIETY

Meeting of May 21, 1931

The regular monthly meeting of the Minneapolis Surgical Society was held in the Lounge on the 20th floor of the Medical Arts Building, on Thursday evening, May 21, having been postponed on account of the State meeting. The meeting was called to order by the President, Dr. A. T. Mann, at 8 p. m. There were 26 members and visitors present.

The scientific program consisted of the following:

Dr. A. T. Mann stated he would like to present a specimen showing dry gangrene of the right hand. The patient was a woman 77 years of age and her history ran back about a year ago when a medical man was called to see her on account of heart trouble. He saw her about once a week for a while, then about December he was called over in a hurry one day and found her in delirium with a bad pulse and a painful area just above the elbow in the upper arm. The forearm was moderately swollen and an induration could be felt running from the wrist toward the elbow along the region of the ulnar artery. The hand the next day was blue and the fingers became black the next day; the thumb, the following day. Her delirium continued for about two weeks. She had a temperature of 102° and when the physician first saw her he thought she had "flu." He thought she was going to die. The line of demarcation soon developed on the line in which it shows now, on the thumb, most of the palm and up the little finger on the outside, all of the fingers and some of the back of the hand. In going over the history carefully, Dr. Mann said he could get no history of a sudden pain. An embolus will practically always give a sudden sharp pain when first arrested, and a thrombus acts just about the same way without the pain. It may be that there was a small embolus, partly occluding, in the region at or above the bifurcation of the main brachial artery just above the elbow followed by an occluding thrombosis.

Dr. Mann said he felt that gangrene of the hand is so rare that the members would be interested in seeing this specimen. As stated, the patient is 77 years old. Both feet are warm. It is now five days since he removed the hand and she has been sitting up in a chair since the third day. The dressing shows a nice warm line and no necrosis. When the amputation was done there were no vessels to tie; no vessels spurted and he thought he might have to amputate higher in the arm. He finally got hold of the ulnar artery, pulled it down and picked at it a little. It bled just a very little and so it was tied, but he thought he could have done the whole operation without tying a single vessel.

DISCUSSION

Dr. E. A. Regnier said that ordinarily one would not expect gangrene in the hand from an embolus of the brachial artery, and one would probably have to explain the presence of gangrene in this case on an arteriosclerotic basis. He had seen a man 78 years of age who had an arteriosclerotic gangrene of the little finger.

Dr. Mann said the patient showed no evidence of this except that the vessels showed obliteration. As soon as she was able to be taken to the X-ray room afterwards, films were taken of all extremities. These showed a moderate atheroma of the arteries in both legs and in both arms, with slight areas of calcareous material.

Dr. J. F. Corbett recalled one case of gangrene of the hand that was, in part at least if not wholly, due to cervical rib. He wondered if there might be something like that in Dr. Mann's case.

Dr. Robert P. Caron read his thesis entitled "Intra-abdominal Local Anesthesia" and showed lantern slides demonstrating the method.

DISCUSSION

Dr. S. R. Maxeiner felt that Dr. Caron's excellent paper should not go entirely without discussion. Dr. Caron's observations were particularly interesting to him and he believed now that, with the popularity of spinal anesthesia, local anesthesia forms an excellent addition to the armamentarium of the surgeon, particularly in those cases in which the anesthesia is not sufficiently lengthy. He stated that at Fort Snelling they had had about 40 operations on the stomach under spinal anesthesia. Many of the spinal anesthesias had not lasted long enough for them to accomplish complete gastric resection, although it is usually adequate for a pyloroplasty or a gastroenterostomy. However, they have been injecting the abdominal wall immediately on opening the abdomen and when the viscera are exposed the splanchnic nerves supplying the organ to be attacked have been blocked. Turning up the colon and omentum, he has deposited novocain near the ligament of Treitz and by blocking the gastrohepatic omentum he has secured profound splanchnic anesthesia which has allowed total gastrectomy without spinal, but when performed conconmitantly with spinal neither the patient nor the operator realizes when the spinal anesthesia is lost. In the performance of Polya operations for recurrent duodenal and gastrojejunal ulcers, anesthesia has been complete at the end of two and a half hours. Dr. Maxeiner felt that in the aged, the toxic, and in those cases constituting the substandard risk, local anesthesia should surely constitute a part of the armamentarium of the operator. He said that he had done the upper stage of the Coffey operation by blocking beneath the pelvic brim, which anesthetized all of the sympathetics to the entire pelvis as demonstrated by Dr. Caron's slides. He usually turned the colon to the midline and infiltrated the pelvic brim and then, turning the colon to the other side, completed the injection entirely around the pelvis. By this anesthesia, the upper stage of the Coffey operation may be done as completely as with general anesthesia. Dr. Maxeiner was of the opinion that all surgeons should be able to block the sympathetics within the abdomen, most failures being due to the fact that surgeons will not learn the fundamentals and do not use the method sufficiently often to remain proficient. The more refined surgical technic demanded by the use of local and spinal anesthesia is just as efficient in the prevention of shock and trauma when spinal or general anesthesia are used.

Dr. Maxeiner expressed congratulations to Dr. Caron upon his excellent paper.

Dr. E. A. Regnier felt that the Society was to be complimented in having Dr. Caron's paper so splendidly presented. After seeing the slides and hearing the paper, Dr. Regnier felt that the biggest thing which Dr. Caron had brought out was the practicability of intra-abdominal local anesthesia, and the focusing of attention on its indications. He stated it was particularly indicated in the aged and debilitated people who were poor risks for general anesthesia and likewise for spinal anesthesia. Dr. Regnier mentioned a recent operation which he had done on a patient 67 years old, with a carcinoma of the pylorus in which a subtotal gastric resection was done entirely under local anesthesia, with a maximum pulse rate of 78 while the patient was on the operating table. Without local anesthesia it would have been difficult to manage a case of this kind. He felt that where most surgeons fail in the use of local anesthesia is in taking fifteen to twenty minutes to obtain splanchnic anesthesia after the abdomen is opened. He feels that he cannot sacrifice this time and hastens to use general anesthesia, thereby failing in his objective.

Dr. Caron, in closing, said he wished to emphasize one point, i.e., in the establishment of splanchnic anesthesia, the perivascular injection is of paramount importance. In other words, if the injection is made right next to the mesenteric blood vessels the anesthesia is more certain.

In the Annual Prize Essay Contest offered by the Minneapolis Surgical Society, the judges had awarded the prize to Mr. Theodore C. Erickson, student in the University of Minnesota Medical School. According to the terms of the contest, the winning essay must be read before a meeting of the Society.

Mr. Theodore C. Erickson read his assay entitled "The Histologic Grading of Squamous-Cell Carcinoma of the Lip," and charts were shown.

DISCUSSION

Dr. J. M. Hayes said he was very much pleased to have Mr. Erickson present this subject. About eleven years ago he had gone over some of these cases and was much impressed with the way in which Dr. Broders gave his prognosis in each case with nothing to guide him but the dusty slides he had taken from the shelves. The records in the histories proved that he was correct in his prognosis in the great majority of the cases. Other pathologists apparently have not been able to follow Broders' method. The essayist has shown that with his limited experience he has done very well with this method of grading. Dr. Bloodgood has stated that he believed this was a decided advancement in the recent studies of malignancy. No doubt both the surgeon and clinician would feel greatly aided by a prognosis as definite as this.

Dr. James Johnson thought this was a very splendid piece of work and congratulated the essayist. He felt it was through this type of work that progress would be made in the handling of carcinoma. He wished, however, to leave one thought with the men, one which had come entirely from clinical experience, and that is that this type of grading had not been safe enough to justify minimizing the operation in any way in the treatment of carcinoma. He felt that, regardless of what the type might be, one still has to rely upon a thorough removal of the growth and the adjacent glands. Dr. Johnson said undoubtedly in time pathology would reach a stage where this type of grading would be more accurate, but at the present time, from the standpoint of treatment, all carcinomas should be given a thorough radical removal.

Dr. Mann said, of course one can never tell when there are secondaries in the glands, and personally he felt that whenever an operation is done on the lip a dissection of the neck should be done also.

Mr. Erickson, in closing, said, in regard to the correlation between the type of operation and the postoperative history in the case, that he had just started working on that phase of the problem and was sorry he had no results to report at this time. He hoped to have some in the next two months. He believed there was really no justification for doing just a local excision on the Grade I group as yet, because most men could not grade these as well as Dr. Broders does. At the Mayo Clinic at least 80 per cent have had excision of the local lymph nodes. Brewer in his work showed the relation between the percentage of five-year cures and the type of operation. He found that where there was no glandular involvement demonstrable, local excision alone gave 66 per cent of five-year cures, while local excision combined with block dissection of the neck gave 92 per cent of five-year cures.

Mr. Erickson said he was very much impressed by the way in which Dr. Broders could grade these carcinomas. Many others have tried other methods of grading which have differed somewhat from Broders' but he thought none of the other methods have shown the merit which Dr. Broders' has shown. Hueper of Chicago has a method of grading, using 20 different items, such as separate characteristics of the cells, but this seems too complicated for practical use.

Dr. O'Brien of the University Hospital, in a survey of the literature on carcinomas of the bladder, concluded that Broders' method of grading gives just as good results in prognosis as clinical judgment based on both clinical findings and the usual pathological data.

Dr. R. R. Cranmer read a paper on "Spinal Anesthesia" and slides of numerous charts were shown.

DISCUSSION

Dr. Martin Nordlund said there were two points with reference to spinal anesthesia which might be of interest and which he would like to have Dr. Cranmer discuss. First, nothing was said in the discussion with reference to the amount of drug which should be administered and particularly what the factors were which would determine this amount. He called attention to Dr. Lunde's method of using 1 mg. for each pound of weight of the patient. Second, he thought it important to consider the cause and the treatment of the nausea which frequently occurs during the operative procedure, following the administration of spinal anesthesia. He called attention to a recent talk by Dr. Wright of the Pharmacology Department of the University of Minnesota before the Hennepin County Medical Society, with reference to stimulants. Dr. Wright emphasized the value of Alpha-lobelin and Metrazol as respiratory stimulants. Dr. Wright stated that he believed these drugs would be of benefit for the nausea thus developed.

Dr. Nordland said in his experience with spinal anesthesia, he believed that these drugs were very effective in preventing the nausea.

Dr. Daniel Bessesen (by invitation) said he would like to add a few points to the discussion. During the last decade a tremendous amount of work had been done on all types of anesthesia and since this work had grown it seemed to him the indications and contraindications had been greatly altered. He felt that the anesthetic may be selected for the individual case and the individual type. Some individuals should be put to sleep. Crile and his associates wish to put most of their goiter cases to sleep. Dr. Bessesen thought blocking should be done in any case where there is a desperate risk. Spinal anesthesia has a great field and the indications and contraindications which Dr. Cranmer has given represent the last work on that subject. He himself had been somewhat surprised at the number of surgeons who do not consider spinal anesthesia contraindicated in peritonitis. He always preferred the Fowler position but these surgeons do not seem to fear using spinal in their cases of peritonitis, after which they are placed in the Trendelenburg position for three hours and then are kept in the flat position for 24 hours without apparent bad results.

Dr. Bessesen said one might wonder if the drop in blood pressure would produce embolus formation. He had not noticed any reported in the literature, and perhaps none had been made by the men using spinal anesthesia.

In regard to the question of headache, Dr. Bessesen believed this is brought on by some change in intracranial pressure. An increase of intracranial pressure may be treated by 6 oz. of magnesium sulphate in the rectum. This may be administered intravenously using 2 c.c. of 50 per cent magnesium sulphate diluted to about a 20 per cent solution. If the lowering of pressure is not successful, the introduction of pituitrin may be found successful.

Dr. Bessesen said it seemed to him as though the deaths from spinal anesthesia have been considered as a mysterious matter. About the only thing one can base this on is the change in blood pressure. If the blood pressure is found to be reduced to a dangerous level then one must rely entirely on stimulating drugs such as ephedrin or pituitrin, or the Trendelenburg position, or the introduction of fluid into the vein; the Trendelenburg and fluids being the more valuable. In cases of paralysis of the ileum, spinal anesthesia has been successful in relieving the ileus.

He felt the general impression was against the use of spinal in cesarean section, for the reason that in these operations one might anticipate more hemorrhage, which might result in a drop in blood pressure.

In regard to nausea, altering the level of the table will sometimes relieve this; also the use of 5 per cent carbon dioxide as advocated by Yandel Henderson.

Dr. Bessesen said the use of spinal anesthesia is fairly well-established in the field of anesthesia.

Dr. H. O. McPheeters said he was interested in what Dr. Cranmer said about spinal in cesarean section. He himself had been so much pleased with the results of spinal anesthesia in obstetrics. So far he had had only nine cases in which he had used it and in some of them it had worked beautifully. He had used "gravocaine" and with that the patient is put in the Fowler position. The directions on the box are to give the spinal with the patient upright and with the feet over the edge of the bed, and wait three or four minutes; but in actual use he had found it better to wait for ten to twelve minutes. The uterine contractions will be scarcely diminished and if they are violent or there is one tremendous pain right after another the labor will continue right on and the woman will hardly know she is having the baby. The relaxation of the perineum is ideal. Dr. McPheeters said he really believed that spinal is going to be the ideal anesthesia for obstetrics.

Dr. Mann asked about hemorrhage in these cases.

Dr. Webb stated that he had an interesting experience with spinal anesthesia day before yesterday. He operated on a patient who had a perforated ulcer of the duodenum. The preoperative diagnosis was questionable; the signs were rather of an acute appendix or gallbladder. The patient had, however, a previous history of ulcer of the stomach. Before he opened the peritoneum he filled the incision with water as had been his custom for many years when perforation is suspected. If there is air in the cavity it will come up through the water and one can know that he must search for perforation of the gastrointestinal tract.

When the peritoneum was opened, no air bubbled through the water in the wound but the water merely went into the abdominal cavity due to the negative pressure produced by the spinal anesthesia and as a result he learned that this test was no longer useful when spinal anesthesia is used. The appendix was found to be acutely inflamed, surrounded with turbid fluid and with fibrin on its tip and the pathological report was "acute appendix." Because, however, of evidence of inflammation about the gallbladder, the incision was extended upward and the perforated ulcer of the duodenum was found and closed in the usual manner and the wound was closed without drainage.

Another point in connection with spinal anesthesia which Dr. Webb wished to bring out is that when using spinal the surgeon expects to get through in a reasonable length of time and he should be able to rely on the observations of the anesthetist. He was of the opinion that the anesthetists of this city do not know as much as they might about spinal anesthesia and experience in observing it does not accumulate. He advocated adoption of a uniform blank through the city for the anesthetists' use so that they will be of more assistance to the surgeons in observing the cases while they are giving their attention to the surgery.

Dr. McPheeters replied there had been no hemorrhage except in one case which he packed to be on the safe side. But he had had hemorrhage in other cases of the same type where he had used no anesthetic at all.

Dr. Mann stated that in looking over some of his own cases, while he had not done very many (he did his first case before the War), he had had no fatalities, but had sometimes been worried. In reviewing the literature, he had found that there have been a few cases of paraplegia following spinal anesthesia. There was one case reported in Europe in which the paraplegia was still present at the time the patient was discharged from the hospital. There was another case in which there was paraplegia which later cleared up. There was retention of urine and in one case the catheter had to be used over one year before the patient recovered his own power again. One man in Paris reported two cases of his own of ocular paresis and collected 84 others. Dr. Mann said one might possibly expect ocular paralysis where a high anesthetic was used but 26 of the cases of ocular paralysis were reported from a clinic in which over 1,500 spinals had been done and in which one of the rules laid down was never to operate above the diaphragm and always to give a low injection.

Regarding the fixation of the novocaine, Dr. Mann said that putting novocaine into spinal fluid makes a solution more heavy than when there was spinal fluid alone, and that is just what most of the spinal anesthesias are—novocaine crystals dissolved in spinal fluid. Then if the patient is turned on his back and in about 5 minutes or so the table is tipped with the patient's head down, that novocaine must be more or less fixed by that time so that it cannot travel, otherwise there is no limit as to where it might run to.

In one clinic there had been 8 deaths in about 11,000 spinal anesthesias. Four of the deaths were due to heart failure within a few minutes, and the other 4 with irritative lesions of ordinary spinal puncture, irritation of the meninges giving rise to headache, pain in the back and meningeal symptoms. Those occurred just a few days later and were attributed to the spinal anesthetic definitely by the man doing them.

Then there is the question of resuscitation. When there is syncope and heart failure, what are you going to do? Then respiration stops too. There has been some work done with injecting adrenalin directly into the heart, with resuscitation of the heart and return of the pulse. Dr. Mann also called attention to another very interesting report from Paris, of the use of caffein after failure with adrenalin injected directly into the heart. In this case they had injected camphorated oil and caffein. They injected the heart with adrenalin and the needle moved a little but the respiration did not come back so they turned the patient over and injected caffein, 50 ctg., into the spinal canal. Their statement was that respiration came back almost at once, and almost immediately with it the heart action. But the injection was cervicodorsal and they had used this region also for their original spinal analgesia.

Dr. Mann said one more thing in the reports interested him very much and that was that Leclerc in Dijon had made a study of cerebrospinal fluid one, two, three, four and six days after spinal injection. He studied 31 cases and found in 9 of them there was an increase in the lymphocytes without much increase in the polymorphonuclears except in one case. In 11 there was increase of albumin one and two days after, and in 15 cases he reported the sugar content was increased. Leclerc went on to say there could be a very definite relationship established between the headaches and the lymphocytosis; and they felt the headaches could be very definitely associated with the conditions in which there was an associated lymphocytosis. Of course there could be other causes too. They found no association in the cases with increase of albumen, and no association with increase in the sugar.

Dr. Webb said one hears a good deal about the "bad risk patients" in this connection, and he wondered how many of the patients are really bad risks. He thought most of them should be good risks unless the surgeon has a reputation for operation on bad risks. He felt a good risk patient deserved the anesthetic which will best enable the surgeon to work for the good of the operation to the patient. Occasionally the "good risk" patient dies from some effect of operation which could have been made easier and he thought in that respect spinal anesthesia deserved a good deal of regard. He did not think that the good risk patient should any longer be advocated as material for keeping up one's technic in use of local anesthesia.

Dr. M. J. Lynch said he would like to know what percentage of the members present, if they had to have a herniotomy, would prefer spinal to local.

Dr. Mann asked for a vote as to the type of anesthesia each would desire in herniotomy on themselves:

6 voted for spinal
16 voted for local
0 voted for ethylene
0 voted for nitrous oxide
1 voted for ether

For removal of the gallbladder:

5 voted for local
13 voted for spinal
3 voted for ether
0 voted for gas—nitrous oxide
0 voted for ethylene

Many did not vote at all.

Dr. Cranmer, replying to Dr. Nordland's question about the dosage of the crystals, said they had been using 150 mg. in the average adult in all operations below the umbilicus, and in children this is reduced to 75 mg., 200 mg. being used in operations in the upper abdomen. Until the first of this year they had not expanded the solution at all and he felt that their results had been just as good; he could not see that this added anything to the procedure. Of course one can get a higher anesthesia with expansion of the anesthetic solution. This expansion is called barbotage.

Dr. Cranmer believed the rate of injection is an important item, and they had tried injecting the solution ½ c.c. a second. He said the height of the anesthesia depends on the amount of solution the crystals are dissolved in, and the speed of injection. The injection is made somewhere between the first and fourth lumbar interspaces, most of them in the third. They had not given ephedrin for a drop in the blood pressure because he thought it is contraindicated. He believed after the spinal injection, when one gets paralysis of the sympathetic nerve supply of the splanchnic vessels, the ephedrin will not affect those blood vessels at all. It reduces the volume of blood in general circulation by its effect on the other blood vessels by forcing more volume of blood into the dilated splanchnic vessels and renders the possibility of cerebral anemia even greater. He said one man had tried out various procedures for combating the drop in blood pressure, and it was reported in the last issue of the *American Journal of Surgery*. This man found that the intravenous injection of normal salt solution is the most reliable method of combating the blood pressure fall.

As Dr. Bessesen has said, there has been considerable mystery about the deaths in spinal anesthesia. It is known, however, that in the larger clinics in the country the mortality rate has been reduced to almost nothing. Wayne Babcock has used it in 1,500 cases with no anesthetic mortality. Dr. Cranmer said he understood there had been some deaths in Minneapolis from spinal anesthesia but he had not talked with any of the men about the cases. One patient, he understood, went through the operation all right and was sent down on the cart with the head lowered. The patient was then put in a Fowler bed and the head of the bed *raised.* The resident came along and saw the patient's condition and endeavored to lower the head of the bed but the crank did not fit and he was unable to get the head down soon enough and the patient passed out. Dr. Cranmer felt that one could not blame the spinal anesthetic for that death, and thought it was just a mistake in proper handling. He felt that it is just as important for one to know the proper handling of the patient as it is to know how much anesthetic to use. The cause of death is cerebral anemia. It was formerly thought that it was due to the fact that the solution injected into the spinal canal gravitated through the spinal fluid and paralyzed the medullary centers. The work of Koster & Kashmann reported in S. G. & O. about two years ago proves that could not be the cause of death. They applied cotton saturated in 10 per cent novocaine to the medulla of animals without causing death.

Dr. Cranmer said he wished to add that the preparation of this paper was in part by Dr. Carl Henrikson, a Fellow in Surgery at the University, who had worked with him in going over the histories of the patients and making the graphs, etc. The paper was presented jointly by Dr. Henrikson and Dr. Cranmer.

Dr. Arthur T. Mann, retiring President, then read his presidential address, entitled "A Short Address on the Passing Year," as follows:

PRESIDENT'S ADDRESS

It is fitting that as President of the Minneapolis Surgical Society I should say a few words now at the close of our interesting year.

I appreciate highly the honor you have conferred upon me in making me your president. It has been an inspiration to have been in close association with such an able body of men as compose this Society; men who are so much in earnest, whose ideals are high and whose accomplishments are steadily increasing. The impetus you have already given to the Society and the work you stand ready to do for it, give promise for a steady growth in its field of usefulness and an enduring increase in its sphere of influence.

Fully aware that the program tonight is a long one, I shall endeavor to confine my remarks and make them as brief as is suitable to the occasion.

Our programs have been full, they have been of high grade and they have been constantly interesting, a fact that has been shown by our inrceasing attendance, by the value and the high tone shown in the discussions. We have had presentations that would have honored any surgical society. They have been varied and they have been constant. There have been given the results of much original work of considerable value, painstaking work, carefully carried through thoughtfully considered and presented in an interesting and attractive form. The moving picture reels and the many lantern slides which have been shown have helped to make the presentations effective. The case reports have been prepared with great care and have added much to the range of the programs.

The material for the programs has been so abundant that it has been impossible to include it all in the programs of the year. So much must go over into the next year that all those who wish for a place on the program may find some difficulty in arranging for it. You should keep this in mind and ask for your places early.

During the present year there has been one evening given over to a clinic and one, our Annual Banquet, with an invited guest of distinction to deliver the surgical address of the year. This seems a good custom to follow.

The clinic, this year, was given at the University Hospital. This clinic, presented by the Surgical Department, with the abundance of the material offered, might well have occupied two evenings. This is the only criticism to offer, for the thirteen speakers on the program had their material well organized and their presentations were admirable.

Our guest speaker, Dr. Clay Ray Murray, of New York, not only made himself felt by giving a brilliant address at the Banquet, but extended his influence widely by giving an address before the Hennepin county Medical Society, another address before the Medical School at the University, and by giving a thoroughly appreciated clinic on "The Modern Treatment of Fractures" to the profession at large, at the Minneapolis General Hospital. The Surgical Society cannot help but be uplifted by bringing here such a man as Dr. Murray.

However, I feel that the usual meetings of the year should be given over to the members of the Society. Those who prepare papers gain more benefit and the Society will have a more substantial growth than in any other way.

To touch some of the other high spots of the year: We have considered the purchase of a lantern of our own and have rejected the idea as we can freely use the lantern here. But we have purchased one of the best movable screens on the market so we can show our pictures anywhere. The transactions of the Society are printed regularly in excellent form in the Medical Journals. And what seems to me to be one of our most important undertakings is in the hands of a committee earnestly working on plans whereby the difficulties and the differences which arise in the settlement of industrial cases and accident cases may be smoothed out and the work of the State Industrial Commission made more equitable for the doctors who are concerned in the care of these cases.

Before closing this brief address, I wish to point out that we are accomplishing one of the main reasons for which this Society exists, one without which it would fail to justify its continuance. And that is the promotion of good fellowship among its members, a better understanding of the surgeons of this city, among whom we work. Nothing can accomplish this so well as the constant association with one another, giving birth as it does to a better understanding of the many fine qualities which these men possess, their earnestness, their high ideals, their right-mindedness. I know of no finer men, in any city, anywhere, than are to be found among the members of this Society.

The meeting adjourned.

H. O. McPheeters, M.D., *Secretary.*

REFINED ANTIPNEUMOCOCCUS SERUM

Since the discovery of the etiologic relationship of the pneumococcus to pneumonia, the search for an effective antipneumococcus serum has continued unabated. Little progress was made in this direction until 1913, when the biologic classification of pneumococci by Dochez and Gillespie provided a rational basis for modern serum therapy in this disease. Reports on the use of refined and concentrated serum preparations bring evidence showing that a considerable reduction in the mortality rate of type I pneumonia is secured by the use of these preparations. Experiments with the type II pneumonia and particularly types III and IV were not favorable to the use of preparations representing these types. In conformity with the evidence, the Council on Pharmacy and Chemistry accepts antipneumococcus serum representing type I but does not accept serums representing other types or mixtures of all types, holding that type I serum alone is worthy of clinical trial. (Jour. A. M. A., May 2, 1931, p. 1505.)

PROGRESS

Abstracts to be submitted to Section Supervisors.

Members are urged to abstract valuable articles which they run across in their reading and send the abstracts to the physicians in charge of the respective sections. In order to avoid duplication it would be well to communicate with one of the section supervisors before the article is abstracted.

EYE, EAR, NOSE AND THROAT

CHRONIC MAXILLARY SINUSITIS: Walter Stevenson, Quincy, Illinois (Arch. of Otolaryngology, No. 4, Vol. 13, April, 1931). This comprehensive article deals in detail with 192 cases that came to operation, and explodes the old adage, "Once a sinus always a sinus."

The chief complaints of patients in order of frequency were as follows:

1. Recurrent head colds—102
2. Nasal discharge and post-nasal dropping—63
3. Pain, usually in maxillary region—30
   Five complained of frontal headache.

Toothache was a common complaint. Several patients had no head symptoms, but had been referred by internists searching for focal infection. Sixteen per cent (thirty-two cases) had originated following dental extractions:

Under diagnosis, nausellumination, X-ray and lavage are discussed. The author thinks the first as valuable as the second. Lavage should not be considered negative unless the washings have been proved so by microscopic examination.

Under treatment the author shows that none of the chronic cases were permanently benefited by puncture and lavage: The Krause (intra-nasal window) was done in all but twenty-two cases. In the remainder a radical operation was needed (Caldwell-Luc). This number (twenty-two) includes five cases which had had the Krause operation done previously, but without a satisfactory result.

The author is not in favor of postoperative washings of the cavity. Shrinking, mild suction and attention to exuberant granulations with silver, gives satisfactory results.

RESULTS

Complete recovery occurred in all but nine cases, which were lost to observation. Focal disease, with the exception of five asthmatics, was relieved or cured.

Details are given concerning operative technic, pathological findings, both gross and microscopic, and a special section in regard to nasal polyps. Several case reports follow. The entire article impresses one as having been written by a man who is absolutely sure of his ground, and with the courage to apply fundamental surgical principles to sinus surgery. Apparently his results justify his methods. The author's summary is given verbatim.

SUMMARY

1. Intranasal surgical intervention is the operation of choice for a primary attack in all chronic infections of the maxillary sinus. Ninety-four and two-tenths per cent of my patients recovered completely following these procedures.

2. The Caldwell-Luc operation has proved satisfactory as a radical operative measure.

3. Transillumination and the roentgen rays are equally effective as diagnostic aids.

4. Except in selected cases, dry treatment is effective in the after-care, and, in my opinion, is the better procedure.

5. Contrary to popular lay opinion, operative treatment for maxillary sinusitis is justified by the results.

6. Focal disease seems to follow this type of infection.

7. In the author's opinion, nasal polyps are associated with maxillary disease more often than with infection of any other sinus, and careful investigation of the maxillary sinus should be made in every case of apparent hyperplastic ethmoiditis. Conservative surgical intervention usually suffices in these cases.

8. Sewall's method of estimating the cytologic content of the maxillary antrum seems to be a distinct advance in the diagnosis of this disease.

9. Injudicious curettement of the sockets of the teeth opening into the maxillary sinus is to be condemned. Curettement should always be followed by suitable surgical intervention to close the wound.

M. W. Wheeler, M.D.

INTRACAPSULAR CATARACT EXTRACTION: Leo F. McAndrews, M.D., Philadelphia (Arch. of Ophthal., Jan., 1931, Vol. 5, No. 1). Three methods of operation are considered (1) Smith, (2) Kalt forceps, (3) Barraquer suction.

Each method is considered in detail with statistics on complications given very fully.

The author is of the opinion that the Smith operation is losing ground and gives the chief disadvantage as frequent loss of vitreous and drawn-up pupil. Advantages given are those of freedom from iritis, lack of secondary operation, and no limit as to type or maturity of cataract.

The Barraquer operation demands special training and experience and is not popular in this country. It can be regarded as being in the experimental stage.

The Kalt forceps method seems to be the most popular method. The originator tears away a large piece of capsule, but some men remove lens intact. An objection is the pull on the ciliary body.

A review of the recent Congress in Amsterdam gives the "modern cataract operation" as being extraction in the capsule with peripheral iridectomy and suture of conjunctival flap.

This article is voluminous and very well written. If there could be any criticism it would be that conclusions on comparative popularity of various operations were not based on the opinions of enough men. A comprehensive questionnaire with wide circulation might have brought out different deductions, but nevertheless it is a very worth-while addition to cataract literature.

K. C. Wold, M.D.

A STUDY OF CALCIUM IN RELATION TO CATARACT—REPORT OF RESEARCH. Daniel B. Kirby, Fellow in Ophthalmology (Presession Volume, The American Academy of Ophthalmology and Otolaryngology, Page 89, 1930). Cataract appears in various forms and the causes of each form are undoubtedly different and dependent on a number of conditions. Cataract, however, is frequently associated with tetany and parathyroid deficiency. In tetany there is usually, and in parathyroid deficiency there is always, a disturbance of calcium metabolism. For this reason an attempt was made to determine the relation of calcium metabolism to cataract, and by this means, if possible, to improve the non-surgical treatment.

The steady level of the calcium in the circulating blood is maintained by the action of the secretion of the parathyroid. When the parathyroid secretion is deficient the serum calcium is found to be below normal. The best parathyroid extract for use in treating calcium deficiency of the blood is parathormone, which is prepared by weak acid hydrolysis of the parathyroids of the ox.

Undoubtedly calcium deficiency in cases of infantile tetany is the cause of the cataracts. Increased knowledge regarding the treatment of infantile tetany has led to a great decrease in the number of cataracts due to this condition. In cases of tetany cataract there is a reduction in the serum, aqueous, and lens calcium content. Once the cataract has formed, administration of calcium and parathormone have no influence in removing the opacity from the lens.

In the lens of senile cataract calcium is greatly increased. The calcium deposition results from:

1. Very slow lens tissue death, dependent on nutritional deficiency.
2. Degeneration of the lens protein with lipoid byproducts.
3. Local concentration of calcium by absorption to the large molecules of the lipoids.
4. Deposition of this calcium by change in the pH toward the alkaline side.

Two series of cases of senile cataract were investigated, one at Bellevue Hospital and the other at the Vanderbilt Clinic. In these cases no calcium deficiency was found in the blood. In some of the patients there was a tendency to hypercalcemia.

It was found that there was no necessity for the administration of calcium salts to patients with cataract, as their blood calcium was normal or very close to normal. Likewise there was no indication for administration of parathormone.

Parathormone was administered to three different series of senile cataracts over varying periods. No evidence of absorption or improvement in vision was observed.

James Brusegard.

HERPES AND ALLIED CONDITIONS: Ralph I. Lloyd (Presession Volume, The American Academy of Ophthalmology and Otolaryngology, Page 161, 1930). Hutchinson first described herpes zoster ophthalmicus in 1866. Since this time other symptoms have been added in the literature to his original description of the disease. Some of these symptoms are: pain in the cutaneous area before the skin eruption, corneal ulceration which appears after the skin eruption, increase of temperature and sweating of the skin of the affected area. Microscopic examination of the Gasserian ganglion shows round cell infiltration, small hemorrhages, and degeneration of the nerve fibers running to the first division of the fifth nerve.

Herpes cornea febrilis is milder than the zoster type. The blister of this disease contains a virus that can transmit the disease to the rabbit cornea, while the zoster blister does not do this.

Keratitis dendritica is an eruption of a group of very fine blisters that lose their epithelial covering and link up to form a linear ulcer resembling the small branch of a tree. It frequently follows an attack of influenza.

Keratitis bullosa has also been placed in the herpetic group.

Animal experimentation and exfoliation after apparent healing strongly suggest that traumatic corneal ulcer belongs in this group. In this case the virus is believed to be present in the subconjunctival sac, lying inert until it is carried beneath the epithelium by the injury.

Keratitis punctata superficialis is a very rare disease which belongs to the herpetic group. It consists of minute lesions scattered over the cornea which tend to remain for some time. It never involves the deeper layers and it is frequently associated with bronchial conditions.

Practically every type of herpes shows a lowered sensitivity of the cornea; for this reason it is very important to keep the affected eye constantly bandaged, both indoors and outside. Radiant dry heat, and ½ or 1 per cent solution of optochin locally should be used. In severe types the Shahan thermophore may also be used. In very severe cases of herpes zoster ophthalmicus an application of the X-ray is the only thing that will relieve pain. Most of the severe cases are accompanied by an increase of intra-ocular tension and the X-ray exerts a favorable influence upon the tension.

The after-effects of severe herpes are: deep and wide corneal scarring, anterior or posterior synechiæ, thinning of the iris, change in color of the iris, partial dilatation of the pupil, and sometimes optic nerve atrophy and paralysis of some of the muscles supplied by the third nerve.

The outstanding symptom of all forms of herpes is lowered sensitivity of the cornea, which can be detected by drawing a wisp of cotton across the cornea. Corneal sensation returns slowly. Glaucoma of lesser degrees is frequently found.

Much animal experimentation has been done with the virus of herpes febrilis and the following facts have been discovered about it: the virus does not stain, passes a filter, can be carried from one rabbit to another, is easily killed by heat, and is effective in weak dilutions.

James Brusegard.

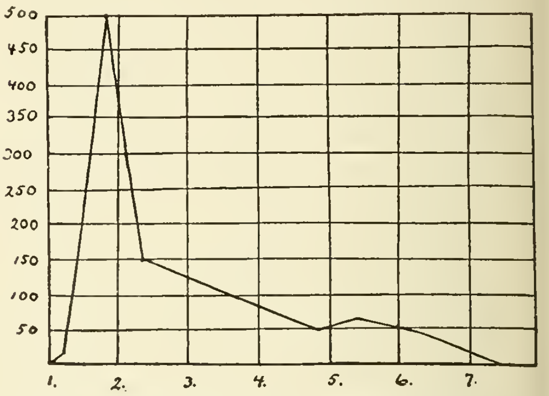
MEDICINE

TUBERCULOSIS ABSTRACTS*

Insomnia is a by-product of our present high-pressure manner of living. Thanks to modern inventions and customs, we are today enabled to enjoy, after a full day's work, another day of recreation which our forebears spent in relaxation or sleep. Normal drowsiness in the evening is fought off in preparation for a night of entertainment. When we finally do retire, sleep will not be successfully wooed. For the tuberculous individual, insomnia is further aggravated by toxemia, discomfort, fear, and worry. Yet rest above all things is necessary for his recovery. W. C. Service outlines the causes, effects, and treatment of insomnia in the April, 1931, American Review of Tuberculosis, from which the following abstracts are derived:

INSOMNIA IN TUBERCULOSIS

Normal sleep is characterized by complete loss of consciousness. The power to make conscious movements wanes first, after which follows the loss of use of the special senses. All voluntary muscles are relaxed, respiration becomes deeper and slower, pulse frequency is lessened, the blood pressure falls, the temperature is lower, secretions are diminished. Of the special senses, hearing is most easily aroused during sleep.



CURVE OF INTENSITY OF SLEEP ACCORDING TO MONNINGHOFF AND PIESBERGEN

The figures along the ordinate show the relative intensity of sleep, measured in milligram-millimeters, expressing the intensity of the sound caused by a falling body necessary to awaken the sleeper. (Modified from Howell's Textbook of Physiology.)

The intensity or depth of sleep increases rapidly during the first two hours and then drops rapidly again, so that by the third hour the sleeper is very near the margin of consciousness, and from that point on the depth of sleep becomes less until awakening occurs.

Insomnia is the inability to secure a sufficiency of normal sleep under favorable conditions. The etiological factors may be grouped under physiological causes, such as pain, dyspnea, cough, pyrexia, gastrointestinal disturbances, toxic states, etc., and psychological causes such as anxiety, neurasthenia, hysteria, confusional states, and compulsion neuroses. True primary insomnia probably never occurs; every complaint of sleeplessness must be investigated for its cause.

TYPES OF INSOMNIA

Five general types of insomnia may be easily recognized, as follows:

1. *Complete absence of sleep.* In tuberculosis, this is most commonly seen during a miliary or acute toxic phase with fever and progressive disease. It is usually of short duration, as complete rest tends to lessen the toxemia, which is usually followed by partial insomnia or even natural sleep.

2. *Sleep on retiring for two or three hours and then wakefulness for the remainder of the night.* This condition is more commonly seen in cases of moderate toxemia. After a profound sleep for about two hours, there is a partial return to near-consciousness. The patient may awaken startled, all senses alert, and without the slightest desire to sleep. After a night of wakefulness, early morning may bring a short sleep from fatigue.

---

*Reprinted from *Tuberculosis Abstracts,* a review for physicians, issued monthly by the National Tuberculosis Association, Vol. IV, No. 7, July, 1931.

3. *Wakefulness for two hours or longer on retiring and finally sleep.* Cases which suffer in this manner are usually the ones who have developed conflicts, especially that of fear. Under the guidance of a sympathetic doctor who understands psychological problems, these patients do extremely well. Fear is an emotion; an emotion is the determining factor of a complex; a complex is an idea plus an emotion. When one complex meets another that is opposed to it, a conflict results. Either a complex or a conflict is, in itself, quite capable of producing insomnia.

4. *Wakefulness on retiring, sleep for two or three hours, and then wakefulness the remainder of the night.* The group so affected represents a combination of the second and third groups. Their inability to sleep on retiring is due to a development of a fear complex or conflict. The inability to stay asleep may be partly due to neuroses, or in part or entirely to the previous damaging effects of the tuberculous toxin.

5. *Dreams: disturbed or restless sleep.* Patients so afflicted usually complain of having a "restless night." Their sleep may be broken by dreams or they may complain of becoming tired in one position and the frequent changing of position may not give them the restful sleep they desire. A heightened irritability of their nervous centers brings their threshold of sleep very near their threshold of consciousness and it consequently takes only the slightest stimulation to arouse them.

EFFECTS OF INSOMNIA

Insomnia affects the body as a whole. After a few restless nights, one notices that the patient is more irritable and complaining than usual. He is restless and finds it difficult to lie in bed. He feels a general lassitude but the nervous irritation prevents relaxation. There is a tired feeling about the eyes and a sense of muscle strain. After several days, extreme tiredness and depression are experienced on arising or weariness may develop a few hours later. Headache may develop in the afternoon, along with sweating, clammy hands, cold feet, and vasomotor disturbances. There may be an increase of fever and of pulse rate. A distressing effect of insomnia is gastro-intestinal disturbances. Food seems to lose its flavor, anorexia may become so marked that there is positive loathing for food. Alvarez has described this condition as a purely nervous indigestion and suggests for its treatment psychotherapy, sedatives, hypnotics, and special diets.

TREATMENT

Accurate diagnosis is essential. When due to physiological causes, a simple correction of them is indicated. Some cases will demand systematic study and sympathetic understanding. The patient in bed is not necessarily at rest. During the state of fatigue, the slightest physical or mental exertion must be considered excessive. Progressive relaxation as described by Jacobson, a method designed to teach the patient to overcome "residual tension," is of great value (see "Tuberculosis Abstract," March, 1930).

Hypnotics and sedatives have been much neglected and often misused. Morphine is a good pain reliever but a poor sleep producer. The author has used several somnifacients and finds that each of them has certain advantages under given conditions. He selects four drugs, such as paraldehyde, dial, bromural, and amytal, and uses them in succession but in equivalent dosage. Each drug is given about three times in succession and then another, until all four have been given, after which the process may be repeated. By this method, a variety is obtained and there is slight danger of developing a tolerance, even if continued indefinitely.

Drug therapy is aided by prolonged tepid baths, general massage, and alcoholic back rubs. Warm or hot drinks at bedtime seem to have a soothing effect in many cases. Black eye-masks prevent the patients being awakened by the light in the morning. Reassurance, or the inspiration of confidence, is, of course, necessary. Low protein diet is beneficial in some cases. Fresh air is a simple and useful remedy. In addition, some cases may profit by bromides, suggestion, persuasion, hypnotism, and perhaps by the analysis of Freud, but limitations and objections are common and the gap in therapy is apparent.—*Insomnia in Tuberculosis, W. C. Service, Am. Rev. of Tuberc., April, 1931.*

CASES OF PULMONARY TUBERCULOSIS WITH EARLY CAVITY FORMATION AND FEW SYMPTOMS: E. Buc (Revuew de la Tuberculose, 1930, X, 1096). "In certain cases one finds completely softened tubercles in the midst of crepitant lung tissue and in these cases the walls of the cavities are smooth and seem to be formed only by lung tissue a little compressed or thickened but without any trace of a false membrane." So wrote Laennec, nearly a hundred years ago.

Buc states that cavities are not always the result of the breaking down of large caseous foci and claims that they may appear very quickly, even in a few days, at the very start of a rapidly developing tuberculosis; in fact, they are often the first demonstrable lesions in cases that eventually become chronic. Without doubt from an anatomic point of view, the loss of substance is caused by the breaking down of a small caseous area, but this produces practically no clinical phenomena.

This cavity is almost always an unexpected discovery during an X-ray examination. As noted above, very few symptoms accompany its formation. There may be a persistent cough which annoys the patient or a small amount of sputum which is very viscid. Sometimes this expectoration is present at the very beginning; in other cases it is preceded by a few acute symptoms, a slight hemoptysis, or a febrile attack lasting a few days, or loss of weight and strength may be noted.

These symptoms are likewise often of very recent origin and have been present only a few weeks before the X-ray shows a cavity about which there can be no doubt, of considerable size. At this time the cavity is the principal lesion seen, it is isolated and solitary.

The broncho-vascular trunks may appear thickened but the parenchyma appears practically normal. Consecutive films show the formation and increase in size of such cavities. At first their contours may be faint and indistinct while the surrounding tissue is not much different from the normal lung. This is Jacquerod's first stage of cavity formation. In other cases, although symptoms have only lasted a few weeks, the cavity is already large, with definite borders, and it is surrounded by an area of lessened density. One might think the cavity was much older than the history of the case warrants. It is impossible to say from the film how long the cavity has existed, but there can be no doubt that it may appear without preceding consolidation of any great extent.

Outside of X-ray study, sputum examination is the most useful diagnostic procedure in these cases. The amount of sputum is usually very slight and patients may even say they do not expectorate; others will admit that they occasionally expectorate a small amount. Sometimes examination of feces will give positive results. When the cavity is present and enlarging, tubercle bacilli are usually found in spite of the paucity of symptoms. The syndrome really consists of three elements: X-ray evidence of cavity, positive sputum and comparatively good general condition. Such cavities may persist unchanged even for an entire year or more. Increase in weight may mislead one as to the seriousness of the condition. The spontaneous disappearance of such cavities is much less rare than is the case with other cavities due to tuberculosis. Often no trace remains. Of twelve cases, six underwent spontaneous cure under sanatorium care. Symphysis of the pleura seems to occur rather frequently in cases with cavities of the type under consideration. Artificial pneumothorax and phrenicectomy are valuable when there is no tendency to spontaneous disappearance, but they are not employed until a period of observation of several months at the sanatorium has demonstrated that no such tendency is present. In suitable cases they are most valuable, as they are followed by rapid disappearance of tubercle bacilli from the sputum. This is very important, since often on account of the appearance of good health and freedom from symptoms these patients are very dangerous to those who live with them.

A. T. Laird, M.D.

PEDIATRICS

THE USE OF RESPIRATORY VACCINE IN THE TREATMENT OF PNEUMONIA IN CHILDREN: Roy P. Forbes, M.D., Denver, Colo., and Charles L. Steinberg, M.D., St. Paul, Minn. (Arch. of Ped., Vol. XLVIII, No. 4, April, 1931.) Vaccine therapy in pneumonia as yet occupies no definite place in the armamentarium of the majority of physicians.

Lambert is apparently the first one to report the use of large doses of vaccine at frequent intervals in the treatment of pneumonia. Lambert's dosage in adults was one to two c.c. of a mixed vaccine containing 1,000 million organisms per c.c. and included:

Pfeiffer's bacillus	200 million per c.c.
Micrococcus catarrhalis	200 million per c.c.
Staphylococcus aureus	200 million per c.c.
Staphylococcus albus	200 million per c.c.
Pneumococcus	100 million per c.c.
Streptococcus	100 million per c.c.

The authors have followed Lambert's technic and give the vaccine routinely at six-hour intervals until lysis occurs, then at 12- or 24-hour intervals for a day or two. The concentrated vaccine which they have been using contains 2,000 million bacteria to the cubic centimeter, or twice the count of Lambert's vaccine. It is prepared by a Pacific Coast laboratory; and from .2 to .5 c.c. is given at six-hour intervals.

The vaccine treated cases frequently appeared less toxic 24 hours after the institution of vaccine therapy. Children who were previously stuporous and refusing all fluids enjoyed a more natural sleep and rest and took fluids when offered.

In uncomplicated cases, the lysis to normal temperature on the fourth or fifth day was noted.

In a series of 50 cases of pneumonia in children treated with large doses of respiratory vaccine at six-hour intervals, a mortality of 18.7 per cent was noted compared with a mortality of 27.3 per cent in the control series of 66 cases. When treatment was instituted within 48 hours of the onset, the mortality noted was 4.6 per cent as compared to 20.6 per cent in the control series. The evidence presented tends to prove that the treatment possesses real value, especially in early pneumonitis. The results in this series are strikingly similar to those obtained by Lambert and by Sutton in adults.

R. N. Andrews, M.D.

EFFICIENCY OF SCARLET FEVER ANTITOXIN: Taketo Tsuda, Mukden, Manchuria, China. (Amer. Jour. of Dis. of Children, Vol. 41, April, 1931, No. 4.) Since Dick and Dochez published their reports on an antitoxin for scarlatina, the use of antitoxin in the treatment of this disease has been generally adopted, and the majority of papers dealing with the subject seem to confirm the belief that antitoxin is effective, at least in removing the toxic symptoms, when an appropriate dose is prescribed at a proper stage of the disease. Prepared by the Hygienic Research Institute, South Manchuria Railway Company, Dairen, 1 c.c. of this preparation is said to neutralize more than 1,000 skin test doses of toxin; the author uses uniformly 40 c.c. for an injection.

The statistics suggest that an injection of a sufficient dose, given within twenty-four hours after the onset of the disease, brings about an absolutely reliable effect, as it reveals a 100 per cent recovery; also that the earlier the treatment, the better the results. Also, an injection within twenty-four hours after the onset prevents complications, and there will be more frequent cases of complications when patients are treated later. In this respect, the effect of the antitoxin is worthy of high appreciation.

The injection should be given as soon as possible, for the reason that the longer the treatment is postponed the less the influence of the antitoxin; no effect is to be expected when a patient is given injections seventy-two hours after the onset of the disease.

R. N. Andrews, M.D.

TUBERCLE BACILLI IN CHILDREN WITH ERYTHEMA NODOSUM:

Arvid Wallgren, M.D., Goteborg, Sweden (Amer. Jour. of Dis. of Children, Vol. 41, No. 4, April, 1931). The idea that erythema nodosum in children depends chiefly on a tuberculous infection has gained ground immensely during the last ten years.

Children with erythema nodosum usually do not cough. It follows that if one wishes to detect tubercle bacilli during this period of the tuberculous disease, they must be looked for in the stomach.

During the past year, the author had an opportunity to examine forty children with erythema nodosum, all but three of whom reacted positively to tuberculin. Of the thirty-seven children who reacted positively to tuberculin, seventeen had tubercle bacilli; in the remaining twenty the results of bacteriologic examination were negative. In the majority of the cases with positive tuberculin reactions there were more or less enlarged hilar shadows.

To sum up the whole question, it follows that children with erythema nodosum who give positive tuberculin reactions often excrete tubercle bacilli. This result proves that enlarged hilar shadows in the positive cases are of tuberculous etiology, and that the children really are suffering from tuberculosis; this ought to be regarded as an argument in favor of the tuberculous nature of the erythema. At the same time these researches yield the valuable information that children with erythema nodosum are often spreaders of infection, and that other children ought to be protected from contamination. Children with erythema nodosum must not go to school for a certain length of time after the disease has developed, and if they are admitted to a hospital they should be isolated.

R. N. Andrews, M.D.

ANTROTOMY IN CHILDREN DURING TONSILLECTOMY:

Dr. Simon Stein, New York (The Laryngoscope, Vol. XLI, Feb. 1931, No. 2). Sinusitis is frequently present and is responsible for a great many diseases and complications of childhood.

This preliminary report is based upon a group of 443 cases of antral infection brought to the author's office for tonsillectomy. The age ranged from one and one-third to ten years. These cases had a sinusitis in addition to the diseased tonsils and adenoids, and the sinuses were drained at the time of tonsillectomy and adenoidectomy.

The symptoms of sinus infection in children are persistent nasal discharge, nasal block, repeated colds, temperature, loss of appetite, poor development, reflex cough, and anemia.

Amongst children who had their tonsils and adenoids removed during the three years previous to this series, 116 out of 140 came back with a persistence of symptoms, which on examination proved to be due to sinus infection.

From then on antrotomy was done in 443 cases at the same time as the tonsillectomy and after one week the following results were noted:

1. The discharge had materially decreased in 103 cases.
2. The discharge had entirely disappeared in 250 cases.
3. The discharge had changed in character from a thick mucous or purulent one to a more fluid type in 90 cases.
4. The symptoms had disappeared entirely in 250 cases.
5. The symptoms were lessened in severity in 193 cases.

The 193 cases who still showed evidence of the infection responded to simple suction and baking under the infra-red lamp, within a period of from one week to three months.

Conclusions:

1. Sinusitis is a very common occurrence in children, and may appear at birth or at any time thereafter.
2. The symptoms are those of nasal obstruction, with discharge, headache, coughs, temperature, under-development, and systemic involvement such as joints or pyelitis, etc.
3. The case showing just a small amount of mucoid discharge may be just as severe in its effect as the one with a thin purulent one.
4. In this group of 443 cases the antral sinuses were drained in all cases brought in with diseased tonsils and adenoids, when either the history or physical findings pointed to a sinus involvement, whether mild or severe in character. This procedure is a perfectly safe one, and has given no untoward results.
5. Constitutional treatment is very important. One should always remember coincident allergic or other conditions which, with the sinuses, give the symptoms of the disease.

Lucian G. Culver, M.D.

POST-VACCINAL ENCEPHALITIS IN INFANCY:

F. T. McNair Scott (Brit. Jour. Child. Dis., 27:17, Dec., 1930). Scott reports the occurrence of post-vaccinal encephalitis developing ten days after vaccination of an infant six months of age. Eight other patients were vaccinated from the same supply of lymph, two being infants of four months, and six being adults whose ages ranged from sixteen to forty-six years. In none of these cases was any complication noted. The case reported by Scott recovered, appearing perfectly normal mentally and physically ten weeks after the onset of the condition. Scott calls attention to the fact that eleven cases of post-vaccinal encephalitis in infants under one year of age have been reported in England since 1923. In Germany and Holland twelve and three cases, respectively, have been recorded as occurring in infancy. A few similar cases are also reported from Sweden, France, Switzerland, and Poland. Scott notes that the cases reported fall into the following five groups according to their clinical picture:

1. Meningitis type, in which symptoms are mainly those of meningitis.
2. Cortical type, in which the outstanding and often the only clinical manifestation is convulsions.
3. Type resembling tetanus, in which signs are trismus and opisthotonos.
4. Brain stem type, resembling encephalitis lethargica, and characterized by drowsiness, ocular palsies, facial palsy and choreic or tonic movements of the limbs.
5. Lower motor neuron type, resembling poliomyelitis.

The mortality varies considerably with the type of case, being much higher in the first three groups (66 to 75 per cent) than in the other two. The condition occurs with exceeding rarity in children, showing an incidence in Europe as estimated by Scott of one case in approximately every 1,800,000 vaccinations.

The author concludes that infants are very liable to small-pox and that the mortality is high, whereas infants are rarely attacked by post-vaccinal encephalitis. It seems right, therefore, to urge the continuation of compulsory vaccination in infancy if performed with precautionary measures as outlined. He ends with the significant quotation from Sir George Newman: "Cases of post-vaccinal encephalitis are more frequent in countries where vaccination is declining than in those in which the proportion of vaccinated persons is high."

C. A. Stewart, M.D.

THE TREATMENT OF EPIDEMIC MENINGITIS: J. B. Neal (New York State Med. Jour., 30:79, Jan., 1930). The Meningitis Division of the Research Laboratory of the New York City Health Department, of which Dr. Neal is a member, does not look with favor upon intensive methods of treatment of meningitis which includes intravenous and intramuscular combined with intraspinal injection of antimeningococcic serum. Their experience has been rather extensive, including the supervision of the care of more than 1,000 cases of epidemic meningitis during the past nineteen years.

The plan of treatment instituted calls for the immediate administration of serum whenever a cloudy spinal fluid is found. Intraspinal injections in amounts of 20 c.c. are given daily thereafter, until at least two successive spinal fluids show no organisms by smear or culture. It is desirable to drain the subarachnoid space as completely as possible, removing 50 to 60 c.c. if possible. The drainage should be done slowly and carefully, especially if the fluid is under considerable pressure. When large amounts of spinal fluid are removed, more serum may be administered. The dosage of antimeningococcic serum given intraspinally depends on the amount of fluid withdrawn, and on the ease with which the serum runs in by gravity. This applies to young as well as to older patients; thus graduated doses adjusted to age are not used for small children. The only condition for which spinal puncture and serum administration is done more often than once every twenty-four hours is limited to cases in which the intraspinal pressure is greatly increased.

At least four doses are usually required, and the average patient received six to eight injections. If symptoms do not improve after two sterile fluids have been obtained, more serum is given. Intravenous and intramuscular injections are used only in cases of meningococcic septicemia, or in cases of meningitis with positive blood cultures or a rash that tends to persist and recur.

From the standpoint of prognosis the cell count itself is of little value, since the outlook is bad if the fluid becomes clear and the organisms persist. A return of the spinal fluid sugar to normal is a favorable sign.

In blocked cases serum may be administered by ventricular taps or cisternal punctures. Neal prefers ventricular taps, since she has seen no immediate harm from such procedures, whereas death from hemorrhage occasionally followed cisternal puncture.

C. A. Stewart, M.D.

SURGERY

IMMEDIATE AND REMOTE END-RESULTS FOLLOWING OPERATIONS ON THE BILIARY PASSAGES: Hans Kment (Bruns Beitrage zur klinischen Chirurgie, 1930:150:534). The author points out that disease of the biliary passages treated by surgical methods usually has a lower mortality—9.22 per cent (Hotz)—than when treated by purely medical non-surgical methods, as 8 to 10 per cent (Tollquist), 10.2 per cent (Jogluttis), 10 per cent (Binder) and 15 per cent (Naunyn).

(A) IMMEDIATE RESULTS FOLLOWING OPERATION

The series of cases discussed in this paper comprises those in which operation was performed in this clinic between 1912 and 1924 and totalled 427 in number. There were twenty-nine deaths, making a mortality of 6.79 per cent exclusive of cases complicated by carcinoma and pancreatitis. This series included many of Schloffer's private cases. The author compared the above mortality with that of Florchen, Suermondt and Enderlens, which varied from 4.5 to 6.6 per cent, and with that of Brentano, Hueck and Fink, which varied from 13.2 per cent to 14.7 per cent.

Many of the cases in this series were serious, with common duct occlusion. This was attributed to the close proximity of the Karlsbad and other watering places. Patients sought non-surgical relief at these places, deferred operation and when finally operated were in advanced stages of biliary tract disease. The average duration of the disease in Schloffer's private cases at the time of operation was six years with a mortality of 9.3 per cent compared with the charity cases of the clinic, in whom the average duration was 3.5 years with a mortality of 5.92 per cent.

Of the above twenty-nine deaths, six were due to peritonitis, five were due to cholangeitis, four pneumonia, one pulmonary gangrene after pneumonia, seven cardiac disease, two shock, one hemorrhage, two parotitis, and pyemia and one pulmonary tuberculosis.

One-third as many deaths occur if operation is performed after the first attack of gall-bladder disease (Finsterer, Anschutz).

Of the above 427 cases, 213 were interval cases in which simple cholecystectomy was done. The mortality was 1.4 per cent. When in addition to simple cholecystectomy, appendectomy, gastric resection, pyloroplasty, etc., were done, the mortality rose to 2.04 per cent.

When operation was performed for acute urgent cases like gall-bladder perforations, empyema, acute common duct occlusions, etc., the mortality rose to 14.5 per cent for 117 cases. When the main bile ducts had to be opened the mortality jumped to 46.1 per cent.

The author had two cases which died twenty-four and thirty-six hours, respectively, after onset of their first attack of biliary disease. Both of these were markedly jaundiced and died of hemorrhage.

Coagulation time of the blood has no relation to depth or degree of jaundice. In the jaundiced patient the bile salt concentration of the blood is never increased to the point where it can inhibit coagulation. The hemorrhagic diathesis is due to functional disturbances of the liver.

A third group of cases reported were the protracted acute or subacute cases with no tendency to heal. These represent cases of stone occlusion of the common duct. Operation was not immediately imperative in these. On the author's series 31.4 per cent of the cases of common duct stones had no icterus; Arnsperger, 15.5 per cent; Pauchet, 30 per cent.

In the cases of fifteen transduodenal choledochotomies performed, the mortality was 13.3 per cent; Lorenz, with 136 cases, 15 per cent. Pancreatic injury never seen by this method. Drainage was always instituted for stones thought to be left behind and in presence of cholangeitis. Stenosis as a result was never seen.

Cholecystostomy was performed in 21 cases as an emergency operation in cases of empyema of the gallbladder and in cases of abscesses in the surrounding region. His mortality was 9.5 per cent. This operation was always followed, usually at the end of four weeks, by the secondary cholecystectomy.

Of the 427 operated cases, 98 were in males and 329 were females, a ratio of 1:3.3.

The occurrence of the first attack of gallbladder disease was in more than 33 per cent of all the cases during pregnancy, parturition or the puerperium. This the author believe to be due to mechanical factors, infection and particularly puerperal infection. In spite of the high cholesteremia, Lichtwitz says, pregnancy and parturition precipitate the first attack but not stone formation, which he believes is pre-existent.

Pregnant and puerperal women with cholecystitis have an especial tendency toward severe complications, like perforation of the gallbladder, empyema and pyemia. The condition is mistaken for puerperal fever. Cholecystectomy is advisable during the first six months of pregnancy. Interruption of pregnancy is contraindicated.

In 243 interval operated cases there were 23 with jaundice in whom no common duct obstruction was found. The jaundice was attributed to spasm of either the sphincter of Oddi or of the duodenum.

Choledocho-duodenostomy was performed in cases with irremovable obstruction in the ampulla of Vater.

Causes of recurrence of symptoms after cholecystectomy were attributed to (a) stenosis of ampulla, (b) duodenal spasm, (c) cholangeitis, (d) overlooked stones, (e) mistaken diagnosis, (f) pancreatitis.

One-third to one-half of all cases of gallbladder disease develop their first attack after forty years of age.

Mortality in cholecystectomy is proportional to age, because of greater duration of the disease.

Gallbladder disease occurs earlier in life in women than in men but the mortality is greater in the latter.

Hypo- and hyperchlorhydria were found about equally frequent in cholecystic disease.

The author uses the oblique incision, parallel to the lower costal border, in his cholecystectomies. In 191 cases answering out of 329 cases operated, eleven, or 5 per cent, developed incisional herniæ. These required drains for infection. Of forty-two cases with pararectus incision, eighteen answered and three, or 16 per cent, had herniæ.

The author used lumbar anesthesia in 143 recent cases.

Prolonged drainage from a wound following simple uncomplicated cholecystectomy is due, not, as commonly believed, to slipping of the ligature on the stump of the cystic duct, but to injury of the so-called ductus hepatocystici (Odermatt), or to vasa aberrantia. The author drains all his wounds.

There were 39 cases of carcinoma of the gallbladder in this series: Twelve (30 per cent) died from the operation (cholecystectomy), six from peritonitis, three from hemorrhage, one from heart failure, two from cachexia. Of fourteen cases with primary carcinoma of the gall bladder, five had icterus and of these, two had metastases to the liver. Two cases (radically operated) lived two years each and the rest (palliatively operated) died within about seven months. Many, however, were relieved of their icterus and life made more tolerable.

In ten of the primary carcinoma cases, stones were found in the gallbladder.

(B) END-RESULTS AFTER OPERATION FOR INFLAMMATORY DISEASES OF THE GALLBLADDER

In this second part of the paper the author reviews the end-results on all the follow-up cases. All these were operated previous to 1924. As criteria of success following cholecystectomy he uses (1) freedom of symptoms, and (2) capability of working, as his yardstick. He received complete reports on 293 cases, or 73.1 per cent of all operated cases. Of these, 91 per cent were completely capable of work and 8.4 were capable either of light work only or were incapable of any work whatsoever. He divided the 293 cases into five groups as follows:

(A) Fully capable of work—250 cases

1. 208 cases (76.6 per cent) completely symptom-free.
2. 29 cases (10.5 per cent) improved.
3. 13 cases (4.7 per cent) slight improvement.

(B) Unhealed cases—23 cases (8.4 per cent)

4. 9 cases (3.2 per cent) symptoms limit amount of work or make them totally incapable of work. Symptoms, however, improved after cholecystectomy.
5. 14 cases (5.1 per cent)—(incapable of any work whatsoever)
    - (a) Recurrent cases.
    - (b) Operation didn't improve condition.
    - (c) Operation made their condition worse.

(C) 18 cases died of intercurrent infection in no way related to their biliary disease.

Two cases unaccounted for by author.

Total 293 cases.

The Lyon method of biliary drainage with $MgSO_4$ and hypophysin was reported good in many cases. It is contraindicated in phlegmonous cholecystitis and acute cases because of danger of perforation.

All cases whose symptoms had not lasted longer than one week previous to operation and who had no previous biliary attack were permanently cured by cholecystectomy.

Of fifty-seven cases on whom cholecystectomy plus hepaticus drainage or transduodenal choledochotomy was performed, forty-one, or 71.9 per cent, could be re-examined. Two, well one year, died of intercurrent disease, as well as two on whom a secondary laparotomy was performed. Of the remaining thirty-seven, twenty-nine (78.4 per cent) were completely healed, four were essentially better and one so much better he is capable of work.

The author believes it is not so much the duration of the disease previous to operation which governs the end-results as the type of the original disease, *i.e.,* frequency of attacks. The greater the frequency of attacks the worse the prognosis.

Of twenty-six cases, originally operated for empyema of the gallbladder, 21.7 per cent could not work. This was attributed to complications like indurative pancreatitis and cholangeitis. The end-results are better if cholecystostomy is done first, followed later by cholecystectomy. If the gallbladder wall is severely involved, *i.e.,* gangrenous, he does cholecystectomy primarily. When bile in these cases is bacteria-free, they may almost always be found in cultures of the wall. The author cannot agree with Rovsing and other Nordic surgeons in doing only cholecystostomy as the operation of choice. He thinks highly of cholecystostomy as an emergency operation.

H. J. Dvorak.

ANURIA—REPORT OF NINE CASES: Daniel N. Eisendrath, Chicago (Jour. of Urol., April, 1931, Vol. XXV, No. 4). Of special interest to the surgeon who deals with urinary diagnosis in surgery, is the report of nine cases with a rather thorough discussion of this subject by the author, from the standpoint of both diagnosis and treatment.

Anuria is grouped in three types: (a) Secretory. (b) Obstructive. (c) Transitional or combination groups of anurias.

The secretory type is due to cessation of secretion proximal to the kidney or within its parenchyma, and caused by a disturbance of circulation proximal to the kidney itself, such as a vascular spasm of the main renal vessels, as the result of stimulation of the splanchnic nerves; or reflex inhibition of secretion, as the result of peripheral irritation, such as after passing of urethral instruments, after sudden evacuation of the bladder, and after ureteral catheterization; or embolism or thrombosis of the main renal vessels of both sides or of one side with reflex irritation of the opposite kidney; or a marked decrease in blood pressure as often seen in shock; or dehydration due to loss of large quantities of fluid, as seen in cholera, severe hemorrhage, intestinal obstruction with repeated emesis; as well as in advanced cardiac decompensation. Disturbances of the renal parenchyma include the various types of nephritis and nephrosis, such as anuria after scarlatina, bichloride, and similar chemical nephroses, and the anuria in pregnancy, and after nephrectomy. In the latter case, the parenchyma changes in the remaining kidney have either been overlooked or underestimated. Prostatectomy may be followed by anuria. The majority of these are due to renal parenchyma changes, but many are best explained by peripheral irritation. Anuria is comparatively rare in bilateral tuberculosis, neoplasms and polycystic disease.

The second, or obstructive type, is due to unilateral block by calculus, stricture, injury to neoplasm with normal opposite kidney, due to reflex inhibition of the secretory activity of the opposite organ; or a unilateral block by calculus, stricture, injury or neoplasm with congenital absence, lack of development, or complete loss of function, as the result of disease or injury, or due to the absence of the opposite kidney as the result of a previous operation; or due to bilateral block by calculus, stricture, etc.

In the third, or transition or combination group of anurias, the author places those which follow transfusion, burns, gas bacillus infection, potassium chlorate poisoning and blackwater fever from malaria, because of the obstructive factor of the concentrated blood in the renal tubules by hemoglobin crystals, and the interference with the secretory activity of the renal parenchyma.

The author then reviews the typical urologic examination, laying stress on the importance of diagnosis before the end of the period of tolerance is reached. By the period of tolerance he means the interval between the time when the anuria is first noticed and the appearance of symptoms of uremia. The examination includes:

(1) Palpation of the abdomen for enlargement of one or both kidneys.

(2) Catheterization of the bladder to determine the absence of urine.

(3) Plain radiography, to determine the presence of

calculus, remembering that about 15 per cent of all renal and ureteral calculi are shadowless.

(4) Cystoscopy and ureteral catheterization. Pyelography is contra-indicated during an anuria, but can be done a few weeks later.

(5) Blood chemistry, to determine non-protein nitrogen contents and creatinin.

The treatment of anuria is listed in the following steps:

(1) Administration of large quantities of fluid.
    (a) By proctoclysis.
    (b) Hypodermoclysis.
    (c) Intravenous administration.
    (d) The use of the duodenal tube.
(2) Nerve blocking—overcoming splanchnic nerve irritation.
(3) Decapsulation.
(4) Ureteral catheterization.
(5) Operative measures.

The nine cases reported are very instructive, and there are nine illustrations.

A. E. Sohmer, M.D.

OPERATIVE TREATMENT OF SYRINGOMYELIA: Dr. G. Ellmer, Tubingen, Germany. (Der Chirurg, Vol. 3, No. 6, March 15, 1931.) The author states in his review of this subject that the operation of syringomyelotomy, which was proposed by Poussepp in 1926, has not been done frequently to date. The literature, up to the summer of 1930, reports sixteen cases, of which two came from German Clinics (Foerster, Schmieden). In almost all of the cases improvement occurred. Oppel, who operated six cases, had one poor result, and Gehuchten reports a case in which there was improvement for several months, but returned to the original condition after one year.

The present author reports a case which he operated over a year ago. A carpenter, age 25, developed an increasing disability of both hands. Small wounds healed slowly; movement of fingers was interfered with, and sensation became dulled, with pain on exposure to cold. These changes were more marked in the left hand than in the right. After one and a half years, it gradually increased, so he was completely disabled from work. His general health was good; the cranial nerves showed a weakness in the facial on the left side; the left pupil and palpebral fissure were larger than the right; there was atrophy of the thenar and hypothenar regions, and in the interosseous spaces; the fingers assumed a claw-like attitude; the right hand showed the same changes, but less marked; motility of fingers was more disturbed on the left side than on the right; there was bilateral hypalgesia; temperature sense was moderately disturbed; the abdominal reflex was absent on the left side, and there was bilateral positive Babinski.

The diagnosis was syringomyelia, pointing to an involvement of the cord in the region from the sixth cervical to the first dorsal segment. Myelography was made; 35 minutes after injecting the contrast fluid suboccipitally, it showed exclusively on the right side, due, no doubt, to the greater involvement of the left side of the cord; after 65 minutes the contrast fluid was halted at the level of the seventh cervical vertebra; two hours later the greater part of the fluid was at the level of the third dorsal vertebra, and after 24 hours it had all passed to lower regions. It gave an indication of the probable location of the intramedullary cyst in the lower cervical region.

Operation was done under an avertin-ether-narcosis; laminectomy from the sixth cervical to the fifth dorsal was made. The dura seemed under tension somewhat and showed but slight pulsation. A small stab incision released fluid under considerable pressure, the fluid spurting up to a height of 5 cm. Enlargement of this incision showed that the intramedullary cyst was entered, and the fluid, therefore, was cyst contents, the high intramedullary pressure pressing the cord against the dura; the wall of the cyst was thin; probing showed the cyst extending for a considerable distance up and down—the exact extent not being determined. A strand of muscle tissue was inserted in the opening to prevent closure by adhesion; the dura was carefully closed and the wound likewise, in layers. Convalescence was smooth.

The day after operation, the patient was rid of the feeling of cold in his hands. There seemed to be better circulation, and they were warmer on discharge from the clinic; five months later there were no further changes; again one year later there were no further changes. Considering that the disease before operation was advancing rather swiftly, the fact that there was a standstill of further progress for a period of a year after operation was enough to justify the same. The earlier the drainage is done, the better would be the result, because it is known that cord tissue once degenerated cannot regenerate.

The other cases reported in the literature also, excepting one, showed definite improvement. In discussing the technic of the operation, the author compares the incision in the posterior median fissure to that in the region of the antero-lateral column, as performed by Oppel; the latter incision being that which is usually done for cordotomy; excepting that for syringomyelia it is lengthwise instead of transverse.

The author concludes by suggesting this operation in cases of advancing syringomyelia; in this way preventing an advance of symptoms, such as would be caused by increasing pressure causing destruction and degeneration of the spinal cord tissue. The latest postoperative report was by Foerster, whose patient, after two years, was practically well.

A. E. Sohmer, M.D.

BOOK REVIEWS

Books listed here become the property of the Ramsey and Hennepin County Medical libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

BOOKS RECEIVED FOR REVIEW

Health on the Farm and in the Village. C.-E. A. Winslow, Dr. P. H. Professor of Public Health, Yale School of Medicine. 281 pages. Illus. Price $1.00. New York: The MacMillan Company, 1931.

Textbook of Histology. Eugene C. Piette, M.D. Pathologist and Director of the Laboratory of the West Suburban Hospital, Oak Park, Illinois, etc. 466 pages. Illus. Price $4.50. Philadelphia: F. A. Davis Company, 1931.

A TEXTBOOK OF SURGERY. John Homans, M.D. 1,195 pages, with 513 illus. Price $9.00. Baltimore: Charles C. Thomas.

The modern tendency of medical textbook writers to serve more as editor than as author is evidence of healthy modesty and is to be commended highly as conducive to reliability and accuracy. This volume is the result of a concerted effort by the department of surgery of Harvard Medical School to provide an adequate textbook of surgery for medical students. Doctor Homans accepts full responsibility for the entire contents and the words are all his, but the essence of most of the chapters was furnished by twenty-three members of the faculty, and they approved each chapter in its final form. Surgery is too great a subject for the compass of any one mind and the authoritative scope of this volume is extended by its collective authorship. It may be worth mentioning that this is one textbook which was not written at the solicitation of a publishing house.

The book is well put together and attractively printed. There are a few typographical errors, as creep into most first editions. The paragraph headings are selectively italicized or printed in bold-face type to facilitate finding a subject one may be seeking. The book is not cumbersome nor so large as to be appalling to the medical student. The illustrations are almost entirely line-drawings, which are not beautifully decorative but admirably serve their purpose of illustrating the subject matter of the text. The author's style is easily readable, concise, and he usually says the things the student wants to know, or at least should want to know. No ambiguities were noted.

The author rarely attempts to teach that which is not learnable from books; there is little space devoted to operative technic. However, certain technical procedures that a medical student is apt to be called upon to do, such as lumbar puncture, are described in detail in smaller type. Anesthesia might have been given a little more consideration. The subject index of twenty-three pages might be even more detailed to enhance the value of the book as a reference volume.

A feature of the book is a brief historical account at the beginning of each chapter. These are invariably interesting, usually instructive, and constitute about the amount of medical history that the average medical student can be persuaded to read at any one time. Another feature of the book is an unusually complete bibliographic index, which gives also many old original references of classic works.

This book represents the best of surgery as practiced in a foremost medical center; a center rarely given to fads nor yet as conservatively reactionary as some enthusiasts would say. It is a textbook from a group whose leadership in the field of medical education has been well recognized. The medical student will find in it the principles of surgery easily grasped; it beautifully fulfills its purpose for him. The internist and specialist may determine from it the practice of present day surgery. The surgeon may read it with profit as a standard with which to compare his own practices. The need for such a volume and the completeness with which this book fills that need justify a prediction for it of widespread circulation and usefulness.

T. Lincoln Hyde, M.D.

WANTED—Salaried appointments for Class A Physicians in all branches of the medical profession. Let us put you in touch with the best man for your opening. Our nation-wide connections enable us to give superior service. Aznoe's National Physicians' Exchange, 30 North Michigan Ave., Chicago. Established 1896. Member The Chicago Association of Commerce.

EXPERIENCED LABORATORY TECHNICIAN wants position in hospital, clinic, or doctor's office. Best references furnished. Address D-137, care Minnesota Medicine.

WANTED—Well trained and active internist to become associated with well established group in Minneapolis. Address D-140, care Minnesota Medicine.

WANTED—Well trained X-ray technician, one with nurse's training preferred, who has had experience, and is also able to handle physiotherapy department, including diathermy and lamp treatment. Lady with several years' experience preferred. Address D-139, care Minnesota Medicine.

MEDICAL SECRETARY desires temporary or permanent position in doctor's office. Minneapolis preferred. Three years' experience. Telephone Gladstone 3635, Minneapolis.

WANTED—Position as medical technician in a hospital or clinic; or position as a technician and office assistant. Minneapolis General Hospital laboratory training and experience. Address D-138, care Minnesota Medicine.

PRESENT DAY PROBLEMS*

L. Sogge, M.D.
Windom, Minnesota

THE scientific and industrial achievements of the first quarter of the present century have so far outdone those of the preceding quarter of a century that they may be typified by a comparison of the automobile to the bicycle; an aëroplane to a toy balloon; a motion picture to a tintype. The progress of America during this period was markedly more important in the field of science, the invention and perfection of mechanical processes, and the extension of knowledge, than in the field of politics. The more formal historians would probably say that the most important event since 1900 was America's participation in the Great War. Any attempt at contradiction puts a heavy burden of proof on the proponent. Nevertheless, it is a reasonable query whether there is not equal importance in the fact that during this period the average man's tenure of life has increased by about seven years. In a history which aims to keep in mind the average man, it may be that the scientists, who, by discoveries in the field of prevention and cure of disease, increased by about 15 per cent that average man's tenure of existence on this earth, multiplied his defenses against disease, and prolonged his existence, should appropriately be given as much mention as the politicians and military leaders who conducted us into and through the Great War.

As a concrete illustration, chosen chiefly because of the coincidence in time and place that gives it vivid concreteness: On the Isthmus of Panama during the early years of this period three things occurred: One, political; a revolution, and some further transactions having to do with the government of the United States. The second, in the field of engineering, the digging of a canal which reduces by 8,000 miles, and by upward of twenty days, the transporting of goods and passengers by water between the Atlantic and Pacific coasts of the United States. The third, in the field of science, the proof that yellow fever is caused by infection from mosquitoes, and the beginning of the wiping of that disease from the face of the earth. This discovery also led to the prevention and cure of other diseases due to animal parasites.

Walter Reed, in August and September of 1900, proved that yellow fever was caused by the mosquito, and Gorgas' achievement more than any one act of government or engineers made possible the digging of the Canal.

Who can say but that Henry Ford as the manufacturer of inexpensive automobiles may have had a more far-reaching effect on the lives of the average Americans than Warren G. Harding; that C. Latham Sholes, who invented the typewriter and thereby was largely responsible for the introduction of women into business offices, was of more fundamental consequence to a larger number of human beings than Joseph G. Cannon; that the discovery of the remedy for diabetes may have done more for human happiness than the entire thirty-one years of Henry Cabot Lodge in the Senate; that the acquisition of the Philippine Islands may have been of less real consequence to the average American than the increase in the effectiveness and abundance of fly-paper and window-screems; that the perfecting of the vacuum cleaner and the electric flat-iron may have meant as much to the average woman as the bringing of woman suffrage?

At the present time there is no difficulty in demonstrating to the satisfaction of most people that a nation's greatest asset is physical and mental health. The prosperity and happiness of a people are largely dependent upon mental and physical vigor. I believe it is also correct that our knowledge of diagnosis, treatment, and prevention of disease is far in advance of its application to the needs of an individual or community. The largest problem, therefore, before the medical profession at this moment is the closing of that gap which will make the application of our present knowledge both available and effective. Any scheme dealing with public programs must be judged ultimately by the effects it has upon the individuals whom it is designed to help. If that is true, a plan of medical service must be judged from the effects upon those in need of medical advice and treatment and the cost of services rendered. Because of the technical character of medical service it is reasonable to insist that it be provided by those who have had training which qualifies them to perform it. The essential feature of a competent and effective medical service is trained and informed personnel. Today, the public has become health conscious and desirous of obtaining the benefits of the present day knowledge regarding disease and its prevention.

---

*Presidential Address presented before the annual meeting of the Minnesota State Medical Association, Minneapolis, May 5, 1931.

We, as a profession, should be responsive. A country which endeavors to regulate by law its industries and railroads and to manage a scheme of compulsory universal education is likely to make an effort to improve and conserve its greatest asset, the health of the people. Whether the scheme to be used will be sound depends to a considerable extent upon the type of leadership in the program. If we are right in assuming that every individual in the community should receive the benefits of modern medical knowledge, and that considerable numbers still do not receive such benefits, it is more than likely that efforts by amateurs, social uplifters, politicians, and others will be made to correct that situation. The fact is that we have now in America a new professional group, the social worker group, with its specialized training and its diversified interests that are as wide as all society. These new professional men and women are professionally interested in poverty and sickness. It is only another step, and a step which they make with enthusiasm, to interest themselves in the medical profession and its problems. The committee on the cost of medical care is one practical result of this intelligent active interest, and when this final report comes will we be like the Trojans, alarmed when their enemy leaped at them from the wooden horse, or will we be ready to lead and guide? It matters not how sincere these efforts are or how serious some of the difficulties in the distribution of medical care may be, there are certain fundamentals which will determine the ultimate success of any plan.

There are several phases to this problem. First, the economic. Second, the professional organization which will provide a proper distribution of professional services to meet effectively the actual needs of the community. No plan of medical care can be fully successful without intelligent public opinion and coöperation based on confidence in those conducting the program. Third, the educational program necessary to keep this personnel abreast of any knowledge and methods constantly being developed in medicine and prevention of disease.

Most attention has recently been directed toward the economic aspect of this problem and an effort has been made to create the impression that the cost of medical care is unreasonably high. All of you are familiar with the fact that at all times an average of 2 per cent of the population is incapacitated and about twice that percentage is impaired or handicapped. The financial loss to the country represented by lost earning power and reduced production totals well over two billions of dollars a year or equivalent to one-half the cost of maintaining the national government. The economic features associated with preventable and premature deaths represents a very large loss which we shall not try to estimate at this time. The cost of medical care per family per year is shown below:

Patent medicine and drugs	$ 25.00
Physician	24.00
Hospital (civil)	15.00
Nursing	8.00
Dentist	6.00
Non-medical practitioner	2.00
	$ 80.00

The total expenditures represent a little over 2 per cent of our national income.

A few illustrations of our national expenditures per family per year follow:

Passenger automobiles	$150.00
Tobacco	67.00
Candy	37.00
Gasoline	37.00

Movies and entertainment	35.00
Soft drinks, ice cream, gum	34.00
Jewelry and furs	29.00
Radio and musical instruments	16.00
Sporting goods, toys, games	16.00
Perfumes, cosmetics, toilet soaps	15.00
	$436.00

These items total about five and one-half times the total cost of all non-governmental health service. The amount expended on tobacco is almost three times as much as that expended for physicians. We spend a great deal more for candy than we do for doctors. Our expenditures for entertainment are twice those for the maintenance of civil hospitals. We spend twice as much for perfumes, cosmetics and toilet soap as we do for nursing. The explanation for that situation is not difficult to find, for the people of the country buy what they are taught to buy. One billion, five hundred thousand dollars are expended each year in that education by means of advertising, and W. E. Humphrey, Federal Trade Commissioner, states that the publication of fraudulent advertising in magazines and newspapers costs the American public about five hundred million dollars annually. It has been estimated conservatively that the vital or human value of the American people, if one were to expend it in monetary value, is about five times the material wealth of the country. The latter is over three billion dollars, which means that the expenditures for all forms of medical service are about two-tenths of one per cent of the human value. In fact, there is every reason to believe that the present expenditures for medical care may be insufficient to create an adequate service. Certainly they are reasonable.

However, the fact that the cost of medical care is not overwhelming does not relieve the medical profession of its responsibility for working out a satisfactory and more universal plan of medical service. Many methods have been employed in different countries to try and solve this difficulty. We have at present twenty-three countries which have adopted the principle of compulsory health insurance, and seventeen countries that have voluntary health insurance. We all know more or less about the effect of the insurance plan. It is time now to study it thoroughly, to see if we want to be tied up by any such plan. It does not follow for one moment that national insurance on a compulsory or voluntary basis is the only method of dealing with this situation. There are many who believe that it is possible to avoid this serious difficulty of national insurance by the development of other schemes which will retain the advantages and strengthen the features of individual and voluntary effort, and that there are fundamental advantages in the American scheme which need to be capitalized and made more widely available, which a governmentally regulated medical service is likely to destroy.

Let me mention a few of these advantages: The number of hospital beds in the United States has increased 127 per cent in the last twenty years. The capital value of hospitals in the country at present is about $4,100,000,000, and this is an increase of 2,500 per cent in twenty-five years. The cost of hospitalization last year was about $12,000,000 as compared with $1,400,000 in 1904. Fifty-eight per cent of the counties in the United States now have general hospitals as compared with 44 per cent in 1920. Visiting and public health nursing, school nursing, care of well babies, pre-natal clinics, etc., indicate further efforts to provide medical care.

Many industries are establishing comprehensive medical services, some on a local insurance basis. Another feature to be mentioned is the tremendous growth of various schemes of voluntary taxation commonly designated by the term "Community Chest." Over 350 cities now have a Community Chest and last year more than $60,000,000 was raised by them for various forms of social and medical relief.

It is hardly necessary to discuss the tremendous expansion in our idea of what constitutes adequate medical care in the light of the present day knowledge. It has been inevitable that the cost of medical care should rise, but the increase in the cost of medical service since the beginning of the century is small compared to the increase in expenditures in many other fields. Let me call to your attention the fact that the national income of this country has increased from thirty-one billion dollars in 1910 to eighty-nine billion in 1928. It is very doubtful whether provision for medical and health work is receiving an undue proportion of that increase when it is recalled that medical knowledge has been increasing at a phenomenal rate and that the largest part of the increase in the cost of medical care arises out of that new knowledge and new methods based on it. Mention need only be made of the growth of hospitals, laboratories, nursing, X-ray, dentistry, physical therapy, and specialists to suggest elements in the greater cost which arises from the great increase in the knowledge required for proper diagnosis and treatment. Allowing for the inevitable increase in the cost of proper medical care there are, however, a number of unnecessary costs which we, as a medical profession, can avoid. Some of these are: unnecessary laboratory work, unnecessary surgery and unnecessary hospitalization, and the public's self-selection of specialists.

In considering medical economics one cannot ignore the problem of the distribution of physicians in rural communities. May I mention only two general features of this question. During the last sixty years the number of gainfully employed persons in this country who were in agricultural pursuits has dropped from 47 to 18 per cent. The contribution of agriculture to national income has dropped from 26 to 9 per cent. It will be noted that whereas 18 per cent of those gainfully employed are still in agriculture they produce only 9 per cent of the national income. Physicians in a society of free competition are bound to react to the economic standards for rural communities and that is probably the largest factor in the uneven distribution of physicians. This problem is not unique in this country. Good roads, the telephone, and the automobile have done much to meet the problem in this country. A satisfactory solution will be found, but we must not resort to methods that are too artificial. There is probably no single solution. However, there are certain general principles that might be emphasized. One of the most important is that of the prevention of disease. Everyone will agree that a considerable portion of illness and disability is preventable. We must do all we can to shift the best interest of the medical profession from ill health to good health. The physician must become a health trainer and advisor as well as a healer. It seems quite clear that the development of a fundamental basic medical service must include provision for the practice of preventive medicine as an integral part of practice. A second important emphasis should be placed upon the basic medical service which should be provided for the entire community, not alone for the small proportion which is under treatment. A third suggestion is the organization of the professional industries. Specializing is an essential part of modern medical service but it is the responsibility of the medical profession to see that those who claim to be specialists are in fact experts in their fields. A fourth and very important feature is to provide ways and means of continuing the education of physicians in practice. This applies to the general practitioner as well as the specialist. The social, economic, and educational features of any program designed to infuse the entire profession with knowledge of new discoveries and the application of new methods should occupy the most thoughtful consideration of the medical educators and practitioners. Knowledge is not distributable in packages like commodities and should be only in the hands of those who are trained to use it.

In conclusion, there are two outstanding trends of our age, the democratic and the scientific. The success of any democracy depends upon leadership. We look for such leadership in law, education, business, and banking and there is no reason why the public should not expect it in medicine. We possess the knowledge and personnel to solve a large national problem and possessing that knowledge we are responsible for working out the satisfactory solution. We cannot hope to enjoy that leadership to which we are rightfully entitled in modern society by constantly opposing the proposals intended to deal with medical problems even when those proposals are vague and obviously unfit and offered by those unfamiliar with the essential character of the problem.

What we need is a constructive program directed and supported by the best brains of the medical profession which will aim to provide and retain leadership in health needs and in the program of medical service through proper organization of the profession. Some scheme of medical post-graduate education, and constructive public policy and publicity—this is the challenge to the organized medical profession in this country. It can be met only by wise, far-seeing, unselfish, constructive leadership. So we can say like the Ancient Ægean Mariner who, when tossed by the storm, prayed to Neptune, "Oh Neptune, thou canst save me, if thou will; thou canst sink me, if thou will; whatever comes I'l keep my rudder true."

UNDULANT FEVER*

ARTHUR C. FORTNEY, M.D.
Saint Paul

DURING the years 1924 and 1925 in the United States (exclusive of Texas, Arizona and New Mexico) ten cases of undulant fever were reported in six widely separated states. During 1928 and in the first five months of 1929 more than 1,000 cases were reported in 42 states. In Minnesota, prior to 1928, six cases were reported; in 1928, twelve cases; 1929, forty-one, and in 1930, sixty-two. This year, up to the present time (March, 1931) seven cases have been reported and verified by positive blood agglutinations at the State Board of Public Health. Thus, the frequency of the disease is becoming more striking, and at a recent meeting of the Health Section of the League of Nations it was stated that undulant fever is the most important problem facing public health workers at the present time.

ETIOLOGY

In December 1886, Colonel Bruce[1] observed minute organisms in a spleen from a patient who had died of undulant fever. A year later he cultivated an organism which he showed to be the etiologic agent of the disease. The name "micrococcus melitensis" was adopted. Soon after it was pointed out that bacillary forms, as well as coccoid forms, occurred.

Ten years later (1897) Bang[2] described an organism causing contagious abortion in animals. He noticed that these organisms, when appearing in infected tissues, often appeared coccoid in shape. After isolation, however, he determined he was dealing with a bacillus and the term "bacillus abortus" was accepted.

For twenty years these organisms were differently named and even considered by bacteriologists to be unrelated. In 1918 Alice Evans[3] showed that these two organisms were morphologically, culturally and biochemically indistinguishable, and serologically closely related. A new classification was therefore necessary. Meyer[4] proposed the name "Brucella," in honor of Bruce; thus, the term "Brucella melitensis." Previous distinction had been maintained by the recognition of the different varieties. Micrococcus melitensis became Brucella melitensis (variety melitensis) and Brucella abortus, variety abortus. The latter type is divided into the porcine and bovine types.

The natural habitat of the melitensis type is in the goat. Texas, New Mexico and Arizona are the only states in the Union in which the melitensis is of much importance.

A survey of the literature shows that the abortus type is found in practically all parts of the world.

Morphologically, these organisms are small, non-encapsulated, non-motile and gram-negative. Coccoid and bacillary forms occur as well as intermediary oval shapes. Culturally, growth takes place slowly in liquid medium, rarely being visible before the fourth day, and occasionally not until the tenth day. On agar, the colonies on first subculture usually make their appearance in from 48 to 72 hours and slowly increase in size. They are non-acid, non-gas forming. By simple agglutination procedures the strains cannot be differentiated.

MODE OF TRANSMISSION

Formerly it was supposed that undulant fever was transmitted solely through the use of milk. However, clinicians who have had experience with a large number of cases found they could not account for all their cases as being due to ingestion of milk. The incidence among doctors and technicians working in laboratories with the organism soon became striking. Likewise, the incidence among veterinarians and farmers increased. Dr. Bonynge[5] reported the disease in an eleven months old infant who had been fed on certified milk. Three other children in the same family, using the same milk, did not have the disease. Either this was a congenital case or contact. Hardy[6] proved that the disease was transmitted by contact. He took a series of guinea pigs, and in one set he shaved the hair and abraided the skin, then applied the organisms. In this group 100 per cent of the pigs developed undulant fever. In a second series the guinea pigs were only shaved and the organism applied. Here 90 per cent of the pigs developed undulant fever. In the third series the hair was only clipped and the organisms applied. Seventy-eight per cent developed undulant fever. In the fourth series the organisms were fed to the animals; only 22 per cent developed the disease. Dr. Carpenter[7] isolated Brucella abortus from tonsils and lymph nodes. He also found that these tissues remained infected longest.

---

*Presented before the Staff of The Charles T. Miller Hospital, Saint Paul, March 3, 1931.

In cattle "contagious abortion" is a misnomer. The disease frequently affects non-pregnant cows, and the disease commonly affects bulls. Calves possess a relative immunity. Ninety per cent of the herds of Connecticut and 86 per cent of the herds of Pennsylvania are said to be infected. Hirschboeck[8] reports that out of 16,319 cattle tested at the University of Minnesota farm school, 4,938 gave strongly positive serological reactions, and 726 reacted in dilution below 1:100 Simpson[9] in examining a group of cattle found 86 per cent of the cows and 100 per cent of the bulls infected. Eight calves gave negative results. It is the belief among veterinarians that the disease may be transmitted to cows by the bull through the seminal route. Organisms have been found in bovine placenta and also in fetuses. Simpson[10] found three cases in men who first went to a genito-urinary clinic, thinking they had Neisserian infections. Sera agglutination was positive. In one case Brucella abortus was recovered from a sinus tract extending through the scrotal wall.

It is highly probable then that the ingestion of milk is not the only source of transmission.

LABORATORY FINDINGS

The most reliable diagnosis of undulant fever is made by the agglutination test, or by the isolation of the organism. Not all cases of proven undulant fever show a positive agglutination. Carpenter and Boak[7] found this discrepancy in 6 per cent of their cases. Once present, however, it remains positive for two to ten years. Frequently sera show a pre-zone; this means that in the lower dilutions sera will not show agglutination, while perfect agglutination will be found in dilution of 1:400 or above. Thus, the importance of running a series of dilutions.

There is some doubt as to the value of the lower titers. However, the consensus of opinion is that in cases with positive agglutinations of 1:80 the definite clinical picture of undulant fever is generally present. Cases with dilutions of 1:40 are usually considered negative, but the physician must consider his case very carefully and be guarded in his statements before giving his opinion, since it is the rule that the titer falls as the patient gets farther along in convalescence. The lower dilutions without symptoms may be an indication of past infection. In those cases of clinical undulant fever which do not show positive agglutination, other laboratory methods of ruling out the disease are available. In this respect recovery of the organism from the blood stream is the next best method. The technic, however, is still in the experimental stage, but promises to be of considerable value. Hardy[11] was able to get 22 positive blood cultures in his series.

Kristensen reported 65 per cent positive blood cultures in his series. Baker[12] reported a case of intermittent hydrarthrosis in which he was able to demonstrate the organisms in both the aspirated fluid and blood culture. Amoss[13] isolated the organism from the stools in a clinically and serologically proven case by agglutination and planting. The complement fixation test has no advantage over the agglutination test and is not as reliable. Guinea pigs and mice are the best laboratory animals for injection. The value of the skin test is also in the experimental stage, but those who are using it feel that it has a distinct diagnostic value. In mild cases the hemoglobin and red blood cell count are not materially changed. A leukopenia with a relative lymphocytosis is a usual finding at some stage of the disease. Carpenter and Boak[7] found on the average a white count of 4,200, with a lymphocytosis as high as 48 per cent. A high proportion of monocytes are often noted, and a polymorphonuclear leukocytosis is often noted at the onset of the acute septic forms.

CLINICAL FEATURES OF THE DISEASE

The incubation period has not been definitely determined. In accidental laboratory infections it varied from 7 to 12 days. The general picture of the disease is one of a bacteremia. Consequently, no clear-cut picture can be made. Giordona[14] and his workers classify the disease as acute and chronic forms, and then divide them into several types, such as septic, neurologic, visceral, glandular and arthritic. Hardy[11] in his series recorded the following nineteen complaints: Weakness, sweating, feverishness, chilliness, rigor, general aches, headache, backache, pain in back of neck, arthralgia, abdominal pain, anorexia, nausea and vomiting, constipation, cough, sore throat, insomnia and loss of weight.

The temperature is surprisingly high in relation to the pulse, appearance and general condition. Patients with fevers of 101° and 104° often have pulses of only 90 and 100, with normal respirations. Furthermore, many patients do not look at all ill in comparison to the temperature. As a matter of fact only when having a chill will they have any discomfort, and during the inter-chill period they will feel well and not appear ill, although the temperatures may be 101° or more. The fever is usually not the true undulating type as one would expect, but more often of the type one sees in tuberculosis; i.e., high in the afternoon with morning remission. In others it may be of the continuous type. Loss of weight is fairly constant, and may be from 10 to 50 pounds.

Very often the symptoms are quite like those of an upper respiratory infection. In the last three patients seen, two had been previously diagnosed as grippe because of sore throats, slight cough, fever and backache. The third patient made her own diagnosis of grippe. However, the presence of a continual fever with chills, sweats and general body aches should put the attending physician on guard for undulant fever.

One would think that in women with repeated abortions, without findings to account for them, undulant fever would be a safe bet. In not a few cases undulant fever has been found, but in the vast majority it could not be diagnosed. Harbinson,[15] in twenty-five such cases, could only find two showing positive agglutination and then only in low dilutions. Carpenter[16] studied blood from twenty-eight women who aborted and also studied twenty-seven fetuses and twenty-eight placentas. In all of these he found not a single case of undulant fever. Simpson,[17] on the other hand, found positive agglutination ranging from 1:80 to 1:329 in five women who aborted repeatedly. Cornell in his series found five positive blood sera, but each patient went on to normal delivery.

On physical examination one may find very few changes. As said before, the appearance of the patient may not at all be any indication of the severity of the disease. Enlargement of the spleen is supposed to be one of the fairly constant findings. Hardy[11] found this organ enlarged only thirty-seven times in 125 cases. In thirty-five cases Giordono found only two with enlarged spleens. Arthritis with swelling and tenderness of joints may be present. Redness, however, is usually absent. Evidence of orchitis, epididymitis, and oöphoritis may be present. In short, the disease may resemble almost anything, and after the diseases that usually cause a given condition have been ruled out, undulant fever should be considered.

PROGNOSIS

The prognosis is good. Hardy[11] reported two deaths due to endocarditis. However, there had been a pre-existing vegetative endocarditis and undulant fever appeared to have lighted up the process, as no organisms were found in the fresh vegetation. Cases of acute endocarditis going on to fatal termination have been reported due to the disease. Harbinson[15] reported one death with necropsy findings. Here there was evidence of a general septicemia. The mortality ranges from 2 to 8 per cent. The degree of titer is no indication of the severity of the disease. Mild cases may have a titer of 1:1280, while very severe cases only 1:80. Duration of the disease varies from four weeks to eight or nine months.

THERAPY

The numerous recommended forms of treatment is an indication of their value. Different dyes, vaccines and serums have been used, some getting results in one case and absolutely failing in another. At present the consensus of opinion seems to be that reliance must be placed for the most part on symptomatic treatment as in certain other infectious diseases.

CASE REPORTS

Case 1.—Mrs. H. M., a housewife, thirty-five years of age, entered the hospital on August 4, 1928. She had been well up to two months prior to admission, when, without any apparent reason, she began to have chills, followed by fever and moderate sweats. With the exception of discomfort during the chills the patient did not have many complaints. The daily chills occurred for about ten days, and then she felt well. Two weeks before hospitalization the chills recurred and kept up until admission.

The family history was not important. In her past history it was brought out that the patient lived in a Saint Paul suburb, and drank milk freely. She had gone through a normal pregnancy and delivered at term three months previously.

Physical examination was negative except for a palpable spleen. On admission her temperature was 104.2 and pulse, 110. During the first part of the stay in the hospital her temperature varied between 99 and 104. During the latter part of the stay her temperature varied from 98.6 in the morning to 102 in the evening. The patient was given a course of acriflavin without much change in the course of her disease.

The urine was negative. On admission the leukocyte count was 6,000; polymorphonuclears, 45 per cent; lymphocytes, 54 per cent; and eosinophiles, 1 per cent. At time of discharge, examination showed the hemoglobin to be 69 per cent; R. B. C., 3,980,000; leukocytes, 4,850; polymorphonuclears, 41 per cent; lymphocytes, 58 per cent, and eosinophiles, 1 per cent. Agglutination for Brucella abortus, 1:3,480. Blood culture was negative. X-ray films of the chest were also negative.

On leaving the hospital the patient had very few complaints, but fluctuation in temperature persisted.

The herd from which the patient obtained milk was examined and a number of cattle were found to show an abortus infection.

Case 2.—Miss H. S., a housemaid, aged 25, was admitted to the hospital on January 28, 1931. She had become ill one and a half weeks before Christmas, at which time she complained of weakness and fatigue, chills and fever. The physician who attended her ordered her to bed, diagnosing her condition as an upper respiratory infection, probably influenza. Although she remained in bed for one week her cough continued. Shortly afterward the chills and sweats returned, and the cough became worse, so she was sent into the hospital, where it was noted that she had nocturnal chills followed by sweats, always occurring between two and three o'clock in the morning. She also complained of some joint aches. However, at no time did the patient appear ill, and she really had few complaints. The temperature had its daily fluctuations—in the morning usually normal, and at night going up as high as 102°; and the pulse fluctuated directly as the temperature, reaching the rate of 120 per minute.

Physical examination was negative except that the spleen was palpable, but not tender.

Urine showed a trace of albumin constantly; the leukocytes in the uncatheterized specimens ranged from 0 to 10 or 15 per high powered field. On admission the leukocytes were 6,750; polymorphonuclears, 57 per cent; lymphocytes, 39 per cent; large mononuclears, 3 per cent; eosinophiles, 1 per cent; hemoglobin, 66 per cent, and red blood cells, 4,360,000. Leukopenia had been persistent and a relative lymphocytosis developed. Later on, the white count was 4,650; polymorphonuclears, 46 per cent; large mononuclears, 4 per cent, and eosinophiles, 2 per cent. The red blood cells were normal. At one time (about February 16) the large mononuclears reached 11 per cent. Sputa had been negative for tubercle bacillus. On January 31, 1931, Brucella melitensis (abortus) was positive in 1:1,280; the Widal negative.

On February 26 the blood was again examined. At this time positive agglutination for bacillus abortus was present in dilutions of 1:640. Also, at this time the Widal test was positive.

The patient stated that when she was two or three years of age her family had typhoid fever, although she was under the impression that she did not have it, nor did she know whether or not she was immunized against typhoid. At any rate, this present condition was not the clinical picture of typhoid. There have been reported cases of cross agglutination between bacillus abortus and bacterium tularense, but the writer was unable to find any literature showing such a cross agglutination as shown in this case. However, every attempt was made to rule out evidence of typhoid, and, except for the Widal, other confirming tests for typhoid, such as examination of the urine and stools for typhoid bacillus were negative.

X-rays of the chest were negative, and the nose and throat examination was negative.

In the beginning, the patient was given iodides intravenously, but she developed an allergic reaction, so this was discontinued. A series of acriflavine was contemplated, but because of her reaction, and because acriflavine usually caused a slight reaction, it was not given. Thus, treatment was entirely symptomatic.

There was very little change in the patient's condition during the first three weeks in the hospital. However, from that time until date of discharge there was a steady improvement in her general condition, and the evening exacerbation of temperature became less, so that for the last ten days of her hospital stay the temperature was never above 98.6°. The spleen was no longer palpable, and all the subjective symptoms disappeared.

The patient's home was in the country. It was noteworthy that those with whom she lived (in the country) had similar colds and the patient suspected she contracted her cold from some one of them. No investigation of those associates was made. It was also learned that while in the country the patient drank a great deal of raw milk, and for that reason the herd of cattle which supplied the family's milk was reported to the State Board of Health for investigation.

Case 3.—Mr. S. O., a male office worker, aged 30, was seen at the Clinic on November 3, 1930, complaining of a cough, night sweats, aching in the muscles of the chest and shoulders. He said he had had, just three weeks previous, what a doctor had called the "grippe." During investigation it was learned that he did not use milk to any extent.

Examination showed his temperature to be 101° and his pulse rate 76. His throat was clear; his heart, negative. The lungs showed occasional crackles in the second left intercostal space at the sternal border, but X-rays of the chest were negative. The spleen was slightly enlarged.

The urine was negative. The blood showed 80 per cent hemoglobin; 4,600,000 red blood cells; 10,100 leukocytes; 44 per cent polymorphonuclears; 53 per cent small lymphocytes, with 1 per cent large mononuclears, 1 per cent eosinophils and 1 per cent non-filamented. Red blood cells were normal. Brucella melitensis agglutination revealed complete agglutination in 1:160 and partial in 1:640. The Widal test was negative.

This patient lived out of the city and no further record of his progress was maintained.

Case 4.—G. A., a male, twenty-eight years of age, a restaurant cook, was first seen at the Clinic on November 22, 1930, when he complained of weakness, backache, loss of appetite and constipation. His family and past histories were negative. He stated that he was married and that his wife had had three full term pregnancies, with no history of miscarriage.

Two weeks previous, the patient contracted an upper respiratory infection ("nose and head stuffed up"), with a sore throat, but no cough. He went to bed for one day and then returned to work, but he continued to have the above mentioned complaints. Before his illness his weight was 145 pounds and on the first visit to the office it was 133.5 pounds.

Examination showed his blood pressure to be 110/75; pulse rate, 85; and the morning temperature, 99.4°. A few days later the morning temperature was still 99.4°. General physical examination was negative except for a questionably enlarged spleen. Nose and throat examination showed definite chronic tonsillitis.

The urine was negative except for the presence of bile. Blood examination showed 82 per cent hemoglobin; 4,690,000 red blood cells; 4,800 leukocytes; 40 per cent polymorphonuclears; 56 per cent lymphocytes, and 4 per cent large mononuclears. The Wassermann test was negative.

The patient was put on salicylates and on December 30, 1930, he was much improved. His temperature was 97.6°. Urine showed positive bile; blood showed 3,480 leukocytes, with 26.4 per cent polymorphonuclears, 66.8 per cent lymphocytes and 5.2 per cent mononuclears. At this examination the spleen was definitely palpable. Agglutination for Brucella melitensis was 1:640.

When last seen at the Clinic the patient was feeling so well that he did not want to return for subsequent examination; hence, his exact condition at present is not known.

SUMMARY

1. Four cases of undulant fever are reported.
2. The disease is more prevalent than is suspected.
3. In any disease of obscure nature with prolonged fever, undulant fever should be ruled out.
4. The disease is probably transmitted by contact as well as by ingestion of milk.
5. A leukopenia with a relative lymphocytosis seems to be a constant blood finding at some stage of the disease.
6. The use of pasteurized milk will help to prevent the spread of the disease.
7. A case of undulant fever is reported, in which a Widal test, three weeks after onset of disease, was negative, but when reexamined at the end of seven weeks was found to be positive. Other tests were made to confirm a diagnosis of typhoid fever, but they were all negative, so the positive Widal must have been due to some peculiar form of cross agglutination.
8. Much remains to be discovered in the line of therapy. Although vaccines and various dyes have been helpful in certain cases, symptomatic treatment at the present time is the favored line of therapy.
9. A review of the literature on undulant fever is presented.

NOTE: Since the writing of this paper there has appeared in the literature a case of undulant fever also showing a positive Widal but without any clinical evidence of typhoid fever. Schilling et al. in the Journal of the American Medical Association for June 6, 1931, reports such a case and ascribes this Hektoen phenomenon to the possibility that the undulant fever infection stimulated not only the specific agglutinins but also the agglutinins for typhoid fever. Gilbert and Colman, in the Journal of Infectious Diseases for April, 1930, have discussed the Hektoen phenomenon in detail. With the possibility, therefore, of both a positive Widal and a positive agglutination for undulant fever being present in the same blood a final diagnosis can only be made by means of further laboratory studies, especially by the isolation of typhoid organisms in the stool or urine.

AGRANULOCYTIC ANGINA*

REPORT OF A CASE

Rudolph C. Logefeil, M.D., M.S.
Minneapolis

THE first cases of agranulocytosis in connection with infection were reported in 1904 by Schwartz,[1] and in 1907 by Turk.[2] From that time until 1922 numerous case reports have appeared in the literature. In that year Schultz[3] described a group of cases under the name of Agranulocytosis, which he thought might be a new disease entity. In reviewing these and other cases, Friedemann[4] in 1923 suggested the name Agranulocytic Angina. The syndrome was characterized by a sudden onset of sore throat, fever, chills and prostration. Later the angina developed into a bleeding gangrenous ulceration of the mouth and throat with a membrane often simulating diphtheria. Enlargement of the liver and spleen, and occasionally some of the lymph glands occurs, all terminating in a fatal pneumonia. Marked leukopenia, sometimes below 1,000, with great diminution or absence of granular leukocytes and relative lymphocytosis, was the characteristic blood picture and source of its name. Since Schultz's article appeared, over seventy-five cases have been reported, some of which showed additional symptoms of ecchymosis, secondary anemia and ulcerating necrosis of esophagus, intestines and genitals, jaundice, coryza, mouth and labial ulcers, variously located abscesses, painful swollen joints, dental caries and root abscesses, mental torpor, etc. Leukopenia and angina are the only findings common to all cases.

The disease has occurred most frequently in middle-aged women. Although the onset is sudden and usually affects those in good health, it may occur in the persons who have been ill sometime with a chronic disease (Klein).[5] The mortality is extremely high, although a few cases with recovery have been reported. When this occurs, the blood picture rapidly returns to normal. This is often followed in a short time by relapse, ending in death. Harkins[6] has collected reports of about 150 cases from the literature, 82 per cent of which ended fatally.

After elimination of the doubtful cases, Hueber[7] finds seventy-nine cases of undoubted agranulocytosis in the literature, sixteen of which were cured. The histories obtained in twenty-five cases show previous severe infectious processes. In fifteen other cases, there had been a feeling of sickness from one to twelve months, with vague symptoms and no evident cause. In twenty-eight cases the bacteriologic examination revealed streptococci, staphylococci, pneumococci and bacillus coli. In the other cases the pathologic-anatomical findings indicate an infectious process, although the bacteriologic examinations were negative.

Autopsy findings were reported in quite a number of the cases, and vary somewhat. Turk's case[2] showed a bone marrow with an occasional hemorrhagic area and few granulocytes. In Stursberg's case,[8] the long bones showed fatty marrow, while Blumer[9] reports a hyperplastic bone marrow. Hueber[7] states that "the findings in the bone marrow and the negative oxidase reaction of the leukocytes indicated a paralysis of the bone marrow," in his case. Thus, a hyperplastic red bone marrow with normal function except for making granulocytes is characteristic.

In several instances marrow was removed from the sternum at various periods of the disease and showed a decrease in the number of cells, especially in the granulocytic elements, during the height of the disease. The erythrocytic part of the bone marrow seemed unaffected in most of the cases. In those instances in which the spleen or lymph glands were enlarged, the notable finding was *no* evidence of leukemia. Many of the cases showed septic foci in various places such as in the gallbladder, a lung abscess, perityphlitis, follicular abscess in the colon, duodenum, liver and rectum, abscessed tooth, and abscessed lymph nodes.

The blood picture is one of a marked leukopenia with an abscence or marked diminution of the polymorphonuclear leukocytes. The lymphocytes are relatively increased up to 100 per cent.

---

*Read before the Minnesota Society of Internal Medicine, Rochester, Minn., Nov. 10, 1930.

Schultz[3] states in his original report that there ire no specific pathological cells. Very little is said in the various case reports about the morphological characteristics of the blood cells. My own case showed a marked relative lymphocyosis, but the remaining granulocytes and the ymphocytes showed no special morphological changes. Some of the cases reported (Paroulek,[10] Jedlicka[11]) showed immature granular eukocytes and undifferentiated embryonic mononuclear cells. I found these cases also associated with severe secondary anemia, clinical hemorrhagic phenomena and severe sepsis, and believe hey are not true cases of agranulocytic angina, but a type of agranulomyeloblastic septicemia. Most cases only showed a slight secondary anemia and a normal plaetelet count. The funcions of the bone marrow were normal except in he manufacture of granulocytes. Roberts[12] reports normoblasts and megakaryocytes present in heir case, but myelocytes and granulocytes are bsent or nearly absent.

Aside from the blood picture, other laboratory ests are variable and of little help in diagnosis. Throat cultures, sputum, and sometimes blood ultures have shown streptococcus hemolyticus n many of the cases. The question of whether his is the primary cause or only a secondary nvader will be discussed later. Some cases howed staphylococcus aureus abscesses. Occaionally pneumococci and micrococci were culured from the tonsillar fossæ. Absence of Vinent's spirilla and fusiform bacillus was noticeble.

I offer the following case report, not because t shows anything especially striking, but rather hat I feel all cases of agranulocytic angina hould be reported, as an aid to help clear up n apparently hazy situation.

CASE REPORT

H. W., a graduate nurse, aged 29, entered Fairview Hospital January 14, 1930. Her chief complaint on enrance was sore throat, fever and general malaise.

About one week before admittance she had had an bscessed tooth lanced. At this time her throat began o get sore. She developed a fever of 103 degrees, with marked general weakness. Difficulty in swallowing deeloped the next day. The angina and general weakess increased and the fever continued, and on January 3 she was advised by her physician to go to the hospital. At this time he found her with a high fever, marked redness and edema of the throat and soft palate, a membrane in the right tonsil fossa, a dry tongue and a general appearance of severe toxicity. There was marked swelling and redness at the point where the abscessed tooth had been lanced.

The only thing of interest in the past history was that while doing nursing at the Fort Snelling Government Hospital about one year before the present illness, she had been severely ill with angina and high fever, and showed at that time a marked leukopenia and relative lymphocytosis. She became increasingly ill for a week and then gradually improved and was back at work again in about a month. She had had measles, mumps, pertussis, inflammatory rheumatism in 1922, tonsillectomy and appendectomy in 1918.

The family history was without significance. Her mother was living and well at the age of 77. Her father had died of carcinoma, and one brother of pulmonary tuberculosis.

On entrance to the hospital the temperature was 101.2 F., pulse 110, and respiration 20 to the minute. Physical examination at this time by her attending physicians showed about the same findings as previously recorded, except, in addition, a number of coarse moist râles scattered throughout both lungs, especially in the lower left lobe. Her general condition was worse and she now had an anxious expression on the face.

The urine had a specific gravity of 1,013, showed a few granular casts but was otherwise normal. The w.b.c. numbered 4,000 with 6 per cent granulocytes, 85 per cent small lymphocytes and 9 per cent large lymphocytes. Morphology of cells was normal. A smear from the throat on this day showed streptococcus hemolyticus. X-ray of the lungs showed a pneumonic consolidation in the lower left lobe. On January 15 her condition was about the same and 5,000 units of diphtheria antitoxin were given.

On January 16 there was clinical evidence of areas of consolidation in both lower lobes, and X-ray showed an extensive pneumonic process in the lower left lung, and a beginning similar condition in the lower right, with a temperature of 104.2, pulse of 128, and respiration 32. The leukocyte count on this day was 3,500 with 26 per cent granulocytes and 74 per cent lymphocytes. She complained of sharp, stabbing pains over the heart, but that organ seemed to be normal. Streptococcus Immunogen (P. D. & Co.) in 0.5 c.c. doses was given and repeated daily thereafter. Solvochin, 2 c.c., was also given intramuscularly.

I saw the patient first on January 17, being called in consultation. I found her extremely ill, with flushed face, pneumonic type of dyspnea, dry tongue, and very toxic. There was a very foul odor to the breath. Her throat was red, swollen and edematous with a greenish-gray-yellow membrane extending from right tonsillar fossa up onto the soft palate with ulceration along its edge. There was definite enlargement of the lymphatic glands in the anterior neck. The lips showed herpes and the lungs a diffuse, bilateral bronchopneumonia. She was bright mentally. Otherwise the examination was negative. Temperature 103.8, pulse 124. respiration 32. The blood picture was normal except the leukocytes were 2,500, 20 per cent granulocytes and 80 per cent lymphocytes. The morphology of cells was normal.

From this time until the date of her death on January 26, her general condition continued to grow worse. The angina increased in severity. On January 20 the whole soft palate looked gangrenous and sloughed off a few days later. On January 24 she became aphonic. Cultures of the throat showed Vincent's spirilla in small numbers. The pneumonic process seemed to clear in some areas, but increased in others. The temperature fluctuated daily between 101 and 104 degrees, the pulse 105 to 124, and respiration 24 to 34. The fluid intake was kept up to 4,000-5,000 daily, with a urinary output of about one-half the intake. The urine at no time showed anything more than a few granular casts. Most of the specimens were entirely clear. Three blood cultures were negative. Daily blood examinations were made which showed a moderate secondary anemia and a persistent leukopenia. The lowest count was on January 18, 1,550, when the patient seemed slightly improved. The following daily counts were: 2,400, 2,500, 3,900, 3,950, and 2,900 (the day before death). The relation of granulocytes to lymphocytes varied. The extremes were 6 per cent granulocytes, 92 per cent lymphocytes, and 26 per cent granulocytes with 7 per cent lymphocytes. There seemed to be no special relationship between the degree of leukopenia and the percentage of granulocytes. There seemed to be no definite relationship between the degree of leukopenia and the general condition of the patient. The leukocytes increased from 2,500 to 3,900 after a direct transfusion of 300 c.c. of whole blood on January 21. There was also slight improvement in the general condition. Another transfusion of 380 c.c. of whole blood was given on January 26, the day of death. Other treatment consisted chiefly in keeping up a high fluid intake, narcotics for pain and rest, diathermy daily to pneumonic areas, citrocarbonate and digitalis, with no definite benefit noted.

Although other conditions, chiefly sepsis, may be accompanied by leukopenia, I feel that this case corresponds closely enough to those described by Schultz to be considered a true case of agranulocytic angina.

Blumer[9] has recently reported a case of sepsis accompanied by an agranulocytic blood picture in which he believes the sepsis is primary and the blood picture a secondary manifestation. This case, however, did not show primarily the typical mucous membrane lesion (the angina).

Schwartz's[1] case of genito-urinary infection from a ruptured renal or perinephritic abscess showed a terminal gingivitis, enlarged submaxillary glands, and a leukopenia of 600 with no granulocytes, but there was no angina.

Turk's[2] case showed a leukopenia of 940 with 93.5 per cent lymphocytes but the clinical picture was quite typical of an acute endocarditis, which was proved by autopsy, and due to staphylococcus.

Cases reported by Stursberg,[8] Marchand[13] and McAlpin[14] appeared clinically to be types of lymphatic leukemia with varying grades of leukopenia and high relative lymphocytosis, but autopsy showed them to be various forms of sepsis with no evidence of leukemia.

Klein[5] reported a case of chronic, multiple arthritis accompanied by gangrenous stomatitis and terminal pneumonia, with a severe leukopenia (175) and no granulocytes found in 200 cells counted.

Hueber[7] in 1929 reported a case of chronic sepsis with severe phlegmonous necrosing tonsillitis and follicular purulent epityphlitis in the appendicular stump after appendectomy, follicular abscesses in the duodenum, colon and rectum, sporadic embolic abscesses in all of the pulmonary sections, tumor of the spleen, and erythroblastic bone marrow, which showed the typical leukopenia and agranulocytosis.

Other cases in the literature could be cited, but these are sufficient to indicate that there are certain individuals whose bone marrow reacts to bacterial infection differently than usual. Many of these cases are probably not true examples of agranulocytic angina.

In Roberts' case[12] the same patient had an agranulocytic response to one type of infection and granulocytic to another.

Paroulek[10] reports an interesting case showing two attacks of septicemia from different causes but with the same blood picture in both cases: leukopenia with disappearance of mature forms from the peripheral blood and appearance of young cells (myeloblasts) showing complete exhaustion of the bone marrow.

The main question is this: is there always first a sepsis whose toxins exhaust or paralyze the manufacturing plant of the granulocytes in the bone marrow with resulting leukopenia, decreased resistance and death, or is the agranulocytic factor in the bone marrow primary and the bacterial invasion and resulting sepsis secondary? If the latter is true, then agranulocytic angina is a separate disease entity with its pathological origin in the bone marrow.

There are conditions of the bone marrow in which all its functions are depressed, such as aplastic anemia. So-called aleukemic type of lymphatic leukemia and aplastic anemia may develop terminal infections, especially of the mouth and throat, and show agranulocytosis. At this stage they would be very difficult to distinguish clinically from true agranulocytic angina. But, surely in the case of the former, the depression of the bone marrow cannot be physiological but rather the resulting action of some toxin. It is well known that toxic chemical substances such as benzol, thorium, X-ray and others damage or paralyze the regenerating powers of the bone marrow. Farley[15] reported seven cases of depressed bone marrow function resulting from arsphenamin treatments. Wheelihan[16] found an agranulocytic aplasia of the bone marrow following the use of inorganic arsenic in a nine year old child who recovered.

So, it is easy to conceive that toxins resulting from sepsis may in acute cases paralyze, or in chronic or repeated acute attacks, exhaust the regenerative powers of the bone marrow. All the functions, or part only, as the formation of granulocytes, may be affected. Where the excessive virulence paralyzes the creative capacity of the bone marrow, no new cells are passed into the blood. The proportion of these cells in the peripheral blood decreases constantly until there is an extreme leukopenia. If the infection is chronic, it irritates the bone marrow constantly until its creative capacity slowly becomes exhausted, which leads to younger and more immature cells passing into the blood. True agranulocytic angina probably represents the first possibility, namely, acute paralysis of the granulocytic factory of the bone marrow by a specific virus, or a non-specific one, or an unaccountable physiological factor, which completely stops the reaction of the bone marrow and possibly also destroys the cells in the peripheral blood.

Roberts' case[12] is pretty strong evidence that the bone marrow change is primary and precedes the sepsis. There was reduction of the granulocytes to 10 per cent four days before the clinical onset and complete disappearance of the granulocytes from the blood stream two days before the clinical onset. They conclude from this that the disease exists in the bone marrow before it appears in the blood stream, and in the blood stream before it appears clinically. In other words, the disease has three onsets: a marrow onset, a blood stream onset, and a clinical onset. A careful study of their case would certainly indicate that this is true, and affords evidence that the marrow loses its power to make granulocytes for some days before the development of sepsis.

Their patient had two separate attacks about two months apart with daily blood studies which gave them a fine opportunity to study the blood picture between and during attacks. Recovery from the first attack is attributed to the quick onset of sepsis due to the invasion of streptococcus hemolyticus, and resultant awakening of the myelocytic activity of the marrow. It appears from this that secondary bacterial invasion may act as a stimulator rather than a depressor of agranulocytic bone marrow function. Their case also illustrates the fact that great decrease or absence of granulocytes may alone result in serious mental and physical collapse with loss of the natural immunity against infection.

Although most cases succumb to the initial attack, remissions of months or years may occur, with recurrent attacks as illustrated by the cases of Roberts,[12] Rutledge,[17] and the author.

Transfusions seem to offer the most help, but the production of an abscess may prove to be a means of reawakening bone marrow activity. Roentgen ray of the long bones and protein shock therapy have been advocated.

CONCLUSIONS

1. Agranulocytic angina or true agranulocytosis may prove to be a definite disease entity with primary pathology in the bone marrow. Another such case has been reported.

2. Agranulocytosis may be caused by or occur with other conditions such as severe acute sepsis, some chronic infections, poisoning from chemical substances, aplastic anemias, and aleukemic blood conditions.

3. *Absence* of morphological changes in the blood cells, immature leukocytes, severe secondary anemia, and hemorrhagic diathesis, with the *presence* of severe ulcerating angina, prostration, and terminal pneumonia are characteristic of true agranulocytic angina and will help to differentiate it from similar conditions.

ELECTRIC BURNS AND SHOCK*

Robert F. McGandy, M.D., F.A.C.S.
Minneapolis

THE rapid development of industrial electricity has been accompanied by an increase in the number of accidents from electricity. This increase, on the other hand, has not paralleled the extensive use of electricity in the household. It has been estimated that 0.5 to 0.9 per cent of all accidents in industry are due to electricity. Power companies have taken care of the increased hazard by the use of safety devices and as a result we find that the vast majority of accidents are due to carelessness.

Contact with electricity either directly or indirectly can cause any of the following:

1. Electric burns of all degrees.
2. Electric shock.
3. Associated trauma such as fractures and wounds from falls, etc.
4. Complications in the form of paralyses either organic or functional.
5. Sequelæ such as scars, deformities, psychoses, neuroses and melancholia.
6. Death.

In the consideration of electric burns I am going to confine my statements to third degree burns, inasmuch as first and second degree burns, such as flash burns, produced as a rule by indirect contact, do not differ materially from similar burns produced by other means. Contact electric burns on the other hand differ from all other types of burns in several ways. First, the heat producing this type of burn is far more intense and as a rule is applied for a short period of time. The temperature of hot cast iron is about 2200°, whereas that of the electric arc is 5500 to 7000°. Second, the relation of the surface spread to the depth of the burn is usually the opposite of other types, namely, an electric contact burn is deep and not so extensive on the surface. A third degree fire burn for example has a widespread area of erythema, an intermediate circle of vesication and a central area of slough. All three zones are ill defined, merge into each other and are seldom very deep. A third degree metal burn is more circumscribed, having a narrow, peripheral ring of erythema and vesication and a fairly well defined central area of necrosis, almost invariably extending down to the subcutaneous tissue. The electric burn is sharply circumscribed and deep. A small burn may have only a blister which if removed and examined closely has a central white area of necrosis and a very narrow ring of hyperemia about it. Larger burns present a central excavated area which is dry, crisp, bloodless, deep and often charred. This central area is surrounded by a zone of pallor or white necrosis which in turn is surrounded by a narrow zone of hyperemia or edema.

Jaffe states that the effect of a current passing through the skin is twofold: First, in passing through the skin, the electric energy is transformed into heat which alters the skin structure producing the so-called "current marking" which he states is specific and of great diagnostic value. Second, free discharge causes the formation of electric sparks which produce burns of the third degree. We usually have a combination of electric burns and current markings. He describes these current markings as being round, oblong or linear, varying from a few millimeters to several centimeters in diameter. The area is slightly elevated and pale gray, grayish white, yellowish gray or yellow. The hair usually is unchanged and one can often see the imprint of the live wire causing the marking on it. In high tension accidents these markings are often obscured by the burns and are best seen after injury from lower voltages. The bullet wound appearance of some contacts is a typical current marking. It is a round hole extending sometimes to the bone and is the result of sudden formation of steam in the tissues which finds its way out under high pressure. Although these markings are frequent yet electrocutions have been observed without any external sign of injury. Histologically the picture is one of necrosis of all tissue involved in the burn, including at times bone. This necrosis is aseptic as a rule and takes place very slowly without pus formation. In the skin proper the corneal layer is compressed and homogeneous if carbonization has not taken place. Carbonization is usually present only at the positive pole. Elongation of the cells is also noted as is seen occasionally in cauterization. This may be due to drying. The so-called electric edema, which forms immediately, is thought to be due to venous thromboses or local paralysis of the blood vessels.

---

*Thesis read before the Minneapolis Surgical Society at its meeting of March 5, 1931.

Jellinek states that blood vessels become friable and brittle. The endothelium is changed and parietal thrombi are attached to the intima. Microscopically there is extensive destruction of the nuclei, especially in the media. Occlusion is common in small arteries. The progressive character of burns is explained by these alterations in the blood vessels at a distance from the site of the injury due to the fact that they are such good conductors.

A peculiar characteristic of these burns at times is their complete painlessness. I recently had a patient who lost one entire hand and had a deep exit burn involving the humerus on the other side and did not require a sedative of any kind. Another feature is the fact that they oftentimes remain unchanged in appearance for days and even weeks and have very little reaction on the surrounding tissue. Toxic absorption is absent. The patient's general health remains unchanged, even in the presence of large areas of decay. These burns are known to take three to five times as long to heal as other burns, yet they possess a remarkable tendency to heal. After a period of latency lasting days or weeks, the necrotic area, which produces little if any suppuration, drops away spontaneously or can be removed without causing any noticeable irritation or particular discomfort to the patient. I have personally removed necrotic fingers and in one instance a wrist without any complaint on the part of the patient and without anesthesia of any kind.

In addition to the usual treatment for third degree burns in general I feel that the local care of this type of burn should be conservative. Solutions and ointments which help dissolve or hasten the removal of the burn eschar are often used. Such solutions are dilute acetic acid, Dakin's solution, saturated solution of magnesium sulphate and twice normal saline. The latter two have of course no place in the treatment of extensive superficial burns but help separate the eschar from the underlying granulation tissue when used late. Some advocate making incisions in the charred skin in lattice-work fashion to hasten the chemical debridement and lessen the chances of absorption. Early surgery in this type of burn as a rule is contraindicated. During the first few days or weeks after an electrical accident we are unable to determine whether tissue which at first shows no sign of injury will continue to do so or whether necrosis may not set in later on. Thromboses have been found at great distances from the burn. Also, the extent of the destruction in the media of blood vessels leaving the intima intact, is difficult to determine. As a result the possibility of the ligature holding and the vessels tearing, thereby causing further hemorrhages, must be considered. Therefore, immediate surgery entails the sacrifice of larger portions of tissue than is necessary, or if too small an amount is removed a second operation is necessitated. Conservative therapy on the other hand compensates the patient for the long healing period by assuring him the best results and the best possible chance of returning to his work. I personally believe that most of these victims are better satisfied if they themselves can see the necessity of removing a portion of their anatomy.

The only indications for immediate surgical procedures are:

1. Lumbar puncture when there is an increased intracranial pressure.
2. Hemorrhage.
3. Need for amputation of a limb or part in exceptional cases.
4. Necessity for primary suture of tendons and nerves in rare instances.

Before considering the subject of electrical shock we should first give some attention to a few details which are of great importance in understanding the wide diversity of results from electrical accidents. There are many factors governing the flow of an electrical current through body tissues. These factors are always present whether the outcome is fatal or otherwise. They are:

1. Voltage and tension of the current.
2. Current flow or amperage.
3. Resistance of the body.
4. Duration of contact.
5. Unipolar or bipolar contact.
6. Current path through the body.
7. Condition of individual susceptibility at moment of contact.

Many authors distinguish between high and low tension currents. Urquhart places anything below 500 volts in one group while Jaffe places the high limit of current at 1,000. Anything above these is considered high tension. Low voltage deaths are common and many physicians forget that the ordinary household current can kill under proper circumstances. The greatest number of deaths occur apparently from contact with voltages between 220 and 1,100 or in the medium zone. High voltage accidents are not quite so apt to cause death as these tensions are more carefully guarded and have a tendency to throw the victim, etc. The number of cycles in alternating current is important, 39 to 150 cycles being the most dangerous. The cardiac muscle is more tolerant to high cycles. Grounding is also more common than bipolar contact in high tension accidents. The current flow or amperage in a given conductor as you all know is its tension divided by the resistance. The amperage, therefore, gives a more accurate account of the action of a current in the body than its tension (voltage). Chapius states that for normal humans direct circuits of from 200 to 250 Ma. and alternating currents from 70 to 80 Ma. are dangerous. Therefore, if the resistance of the skin is less than 1,200 ohms an alternating current of 110 volts can be fatal, since the intensity would then be 90 Ma.

The high natural resistance of the body is our protective measure to the passage of an electrical current. Resistance is made up of the resistance of the skin at the point of entry and exit plus the resistance of the intervening tissue. Skin is surpassed in resistance only by that of bone. In order we can place the various resistances as bone, skin, cartilage, tendon, the various organs and finally the body fluids. Blood vessels are very good conductors. Many other factors enter to raise or lower skin resistance. Thick, dry skin covered by hair has a relatively high resistance. Moisture such as perspiration and wet clothing lower the skin resistance.

The duration of contact is apparently of great importance. Ventricular fibrillation can be set up in a dog in one-tenth to one-third of a second. Respiration can be stopped almost immediately. In considering the relation of current density to duration of contact, it should be kept in mind that the effects on the heart and nervous system seem to be opposite. Currents of low density seem to have a profound effect on the heart if it is in the current path and little effect on the nervous system. The reverse is true of high density currents. Bipolar contacts are usually more dangerous than unipolar contacts. The current spreads radially from the point of entrance to be collected again at the point of exit from the body. The greatest density is, therefore, at these two points. In unipolar contacts some other part of the body must be suitably grounded for current flow to take place. In bipolar contacts the violent muscular contractions may increase the pressure and duration of contact.

The path of a current through the body is determined by the portions of the body making contact and the resistance of the intervening tissue. Body fluid resistance is low and negligible, as is also that of the blood vessels, and these facts oftentimes determine the course of the current. The current is more apt to go lengthwise through the muscles because of the resistance of the intermuscular fascia to transverse travel. Thus, whether the heart is in the current pathway is of extreme importance. Houston found that 6 amperes of direct current at 115 volts could be applied to a dog's brain without producing death when the path was through the head only, but that only a few tenths of an ampere at this voltage is fatal if the heart is in the pathway. The existence of an idiosyncrasy to electric currents in humans is doubtful. Ventricular fibrillation can be induced easier in depressed and sickly dogs than in vigorous ones. Status lymphaticus, hyperthyroidism, general debility and depressed physical states increase the susceptibility. Surprise and unpreparedness increase the possibility of fatal outcome. These brief facts help us to understand why some men die following low voltage contacts and others are able to resume work immediately after encountering high voltages.

Jaeger states that electric shock is similar to concussion of the brain. Its severity and duration vary within wide limits. Some retain consciousness while others immediately are rendered unconscious. It is said that unconsciousness is immediate in legal electrocution. In industrial accidents it may be of short duration, last for hours or even days and the individual pass finally into a comatose condition, ending in convulsions and death. Others regain consciousness and are able to immediately resume work if no severe injuries have been inflicted. Unconsciousness is more common in accidents due to currents of high tension than in those due to low voltage. Restlessness is common following electrical accidents. It is in these cases of restlessness, coma, etc., where there is a cerebral edema and an increased intracranial pressure that Jellinek advocates spinal puncture and reports many cases with recovery in what seemed to be otherwise fatal accidents.

The pathological picture is not definitely known. In an autopsy performed following a legal electrocution, Langworthy in Baltimore describes alterations of the Nissl substance in the cytoplasm of the nerve cells and a definite shrinkage of the nuclei. This nerve cell injury was diffuse and occurred particularly in the region of the medulla. Others report chromatolysis of the ganglion cells, rupture of and occasionally shrinkage of the cells. Spitzka and Radasch sectioned brains of five legally electrocuted criminals and reported peculiar areas in the region of the small blood vessels in the brain, having a rarefied zone and a peripheral condensed one. They explained these areas on the basis of a sudden liberation of gas bubbles either by electrolytic action or from excessive temperature. Peripheral nerve changes consist apparently of an irritability and lost conductivity. In severe cases the nerves became friable and yellowish gray or are carbonized. The so-called electric cataract and optic atrophy are really a complication or sequelæ of electrical accidents. These are noted especially when the current has passed through the vicinity of the eyes. Changes in the heart are apparently functional alterations which explains the mechanism of death in electrical shock. Most of the observations are based on animal experiments. In cats and dogs an inhibition takes place immediately with low tension currents followed by a fibrillation when the current is broken. The blood pressure rises slightly and then drops and continues to do so after the current is broken. The fibrillating dog's heart does not recover and hence death is immediate. Severing the vagi does not influence its occurrence and hence it apparently results from a direct action on the muscle fibers or ganglion cells in the heart. Ventricular fibrillation has never been demonstrated in humans but is thought to occur. High tension currents on the other hand do not cause fibrillation. When such a current is closed the heart action stops immediately only to be resumed when the circuit is opened, if the current is not applied too long. Arterial pressure then rises again and contractions continue. These contractions continue until paralysis of respiration leads to a gradual decline in blood pressure. This respiratory paralysis which is central in origin is one of the common causes of death in electrical shock of high voltage. Spilsbury compares this respiratory paralysis with that following a blow on the upper abdomen, an irritation of the nasal or pharyngeal mucosa or an unexpected submersion in cold water. He believes a sensory stimulation of the nerves of the skin leads to a reflex paresis of the respiratory center. If the center is not charred or destroyed the chances are very great for recovery, as is demonstrated so clearly both in animals and humans through the prolonged use of artificial respiration.

With the exception of the kidney where an albuminuria and a hemoglobinuria is noticed following an electric shock the changes in other organs are negligible. This albuminuria is thought to be due to toxic products from an abnormal protein cleavage and not due to trauma caused by electricity. It has been noted immediately following legal electrocution. This condition clears up in three days where following industrial accident the victim has lived.

Electricity seems to have some effect upon the coagulability of blood. Alternating current apparently hastens it while direct current delays it. A leukocytosis is common following an electric shock.

From the foregoing statements it readily appears that death from electricity, disregarding the cases in which actual destruction of tissues is so extensive as to be incompatible with life, is due to paralysis of the respiratory center or inhibition of heart action. Urquhart adds to this, death by asphyxiation due to prolonged tetanus, which he observed so commonly in animals.

Concerning the treatment of electric shock the only measure holding any hope is apparently artificial respiration. This should be instituted immediately and kept up until the patient survives or rigor mortis sets in. This makes possible the resuscitation of the paralyzed respiratory center. The passive movements of the chest will also produce slight circulation which together with the ventilating of the blood is often sufficient to revive the vital centers. Power companies at the present time carefully instruct their employes in the proper use of prone pressure resuscitation and physicians called in these emergencies should take advantage of this expert assistance and thereby give the unfortunate victim the greatest possible chance of recovery.

FACTORS OF IMPORTANCE IN THE DIFFERENTIAL DIAGNOSIS OF CHOLECYSTIC DISEASE AND PEPTIC ULCER*

Andrew B. Rivers, M.D.
Division of Medicine, The Mayo Clinic
and
James B. Mason, M.D.
Fellow in Surgery, The Mayo Foundation
Rochester, Minnesota

CHOLECYSTIC disease and peptic ulcer are probably the most common of the organic causes of indigestion. Failure to recognize the complications of such lesions, or the fact that a peptic ulcer and cholecystic disease are associated may result in advising treatment detrimental rather than helpful to the patient. Such treatment may delay rather than hasten return to health, and it may actually jeopardize the chances of eventual recovery.

If peptic ulcer and cholecystic disease are associated, even the most careful observation in hospital may fail to clarify entirely the diagnosis. In a review of a large series of surgically verified cases of associated cholecystic disease and peptic ulcer we[1] found that in 13.6 per cent of cases of duodenal ulcer there was evidence of cholecystic disease (Fig. 1). In cases of gastric ulcer pathologic changes were found in the gallbladder or bile ducts in 7.8 per cent. In a series of 1,026 cases of proved cholecystic disease 7.1 per cent showed evidence of a peptic lesion. The recognition of disease in the gallbladder and peptic ulcer in association is of obvious significance, because non-surgical methods of treatment under such conditions would usually be quite useless.

By collaboration with the roentgenologist valuable assistance in the diagnosis of peptic ulcer and cholecystic disease is usually obtainable. Peptic ulceration may be demonstrated by the fluoroscope and, by perfection of technic and an increased amount of experience, cholecystography has now become a recognized aid in the detection of disturbed cholecystic function or gallstones.

Analysis of gastric and duodenal contents, tests of the stool, and various methods of ascertaining the unimpeded flow of bile from the liver or gallbladder into the intestines are at our disposal and should be utilized to accumulate all possible data for the diagnosis of the unusual case. The modern aids to diagnosis, however, must not supplant the carefully evaluated history if grave errors in diagnosis are to be avoided.

It is important to recognize the syndrome usually brought about by non-complicated peptic or cholecystic lesions, as well as the symptoms which may arise if such lesions are complicated. If an attempt is made to formulate a syndrome invariably characteristic of peptic ulcer or cholecystic disease, regardless of the presence or absence of complication, great difficulty may be experienced in satisfactorily explaining a given syndrome.

Changes in the syndrome of peptic ulcer occur with the development of complications, such as disturbances in mechanics, the natural sequence of pyloric obstruction, or the involvement of adjacent organs through chronic or subacute perforation. With the development of complications of chronic perforation or obstruction the general characteristics of the previously established syndrome usually change. The patient himself is aware that his symptoms are different and thus not infrequently is induced to consult his physician. The clock-like precision of the syndrome disappears. Whereas previously the pain was well localized to a small epigastric area it now has become more diffuse, shifting toward the right upper quadrant, upward into the thorax or through to the back. The pain may be more severe and more persistent. The ingestion of food and alkali, which formerly promptly dissipated the pain, now scarcely affects it at all. The element of periodicity practically disappears, there being trouble every day. There are still periods when the symptoms are somewhat less severe, but the long periods of intermission are no more noticeable. There may be intensification of symptoms after meals or vomiting may be the presenting complaint. Should the patient be examined at such a time there might be but little in the history to suggest ulcer and unless a careful examination is taken an error in diagnosis may result. It is obvious therefore that to make an exact diagnosis it is essential to be able to recognize the symptoms of complicated ulcer.

---

*Abstract of University of Minnesota Extension Lecture given at Hibbing, Minnesota, May 7, 1931.

If a patient is examined during a period when the ulcer is producing slight obstruction, or is in an acute or subacute condition, or if it is penetrating deeply into the wall of the viscus, symptoms may be elicited that may well be mistaken for those caused by cholecystic disease. A carefully taken, complete history, however, will usually disclose that the initial syndrome was different from that presently noted and frequently the period in which such changes occurred can be exactly determined.

The diagnosis of peptic ulcer and cholecystic disease and the differential diagnosis of these two lesions is usually not difficult if carefully controlled laboratory methods are evaluated with judiciously taken anamnesis, and careful chronologic tabulation of the history from the inception of the distress.

Cholecystic disease may manifest its presence in several ways. The symptoms arising from a definitely infected gallbladder or a gallbladder that contains stones may be quite different from those that arise from a mildly diseased organ, giving only reflex symptoms referable to the gastro-intestinal tract. The symptoms of cholecystic disease are more easily evaluated if they are subdivided as follows:

1. Symptoms arising from the inflamed gallbladder itself, which include localized distress, pain, tenderness, and rigidity of the muscles in the upper right quadrant of the abdomen arising from the infected wall of the gallbladder. Involvement of surrounding contiguous organs might intensify or complicate these complaints. An infected gallbladder almost invariably produces symptoms sufficiently definite to permit a diagnosis without difficulty.

2. Symptoms arising from gallstones blocking a bile duct. The migration of a stone into the cystic duct usually produces severe symptoms. Colicky epigastric or right upper abdominal pain is common. Opiates may be necessary to obtain relief. If the stone blocks the cystic duct, chills, fever and jaundice may be added to the symptoms. Coincident with the jaundice, itching may develop, and the coagulation factors of the blood may be disturbed.

3. Symptoms arising as so-called reflex of the gallbladder. These ill-defined symptoms, including upper abdominal flatulence and belching with nausea, particularly after the ingestion of apples, onions, and fried fat food. Vomiting after meals is present. It should be pointed out, however, that such a syndrome is unreliable in indicating the presence of a diseased gallbladder. Nervous indigestion, food allergy, constipation and many other conditions have a similar syndrome.

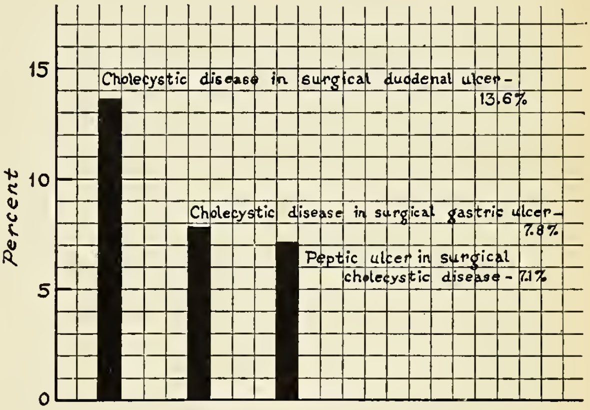

Fig. 1. Incidence of cholecystic disease in surgical gastric and duodenal ulcer, and of peptic ulcer in surgical cholecystic disease.

It is a curious fact that whereas the development of complications may be perplexing in the diagnosis of ulcer, the development of more serious disease in the gallbladder usually facilitates diagnosis. The differential diagnosis of the two conditions could, in many instances, be facilitated if, in a careful search of the patient's history, the present syndrome and the initial syndrome are compared. The development of complications or the period in which such complications arose could thus frequently be ascertained.

ABSTRACTS OF ILLUSTRATIVE CASES

Case 1. Cholecystoduodenal fistula.—A woman, aged sixty-two years, had experienced severe upper abdominal pain and jaundice twenty years previously. There had been no further trouble until fifteen months before admission. At this time she had had very severe pain in the upper right quadrant of the abdomen, which penetrated through to the back and was associated with chills and vomiting. There was no icterus or fever. She remained in bed for three weeks and required several hypodermic injections of morphine. Following this on three occasions she noticed several medium-sized stones in the stool. Further attacks of colic, one six weeks and one three weeks before registration, had occurred. There had also been vomiting, moderate flatulence, and residual soreness in the upper part of the abdomen. A diagnosis was made of chronic cholecystic disease.

General and laboratory data were negative except for a leukocyte count of 15,000. At operation a markedly inflamed gallbladder perforating into the duodenum and associated chronic appendicitis were found. Cholecystectomy and appendectomy were performed and the fistula was repaired.

In this case there was no difficulty in localizing the disease to the gallbladder because the history contained definite evidence incriminating this organ. The pain in the right upper quadrant, referred through to the back associated with chills and vomiting, and requiring hypodermics, furnished evidence of cholecystic disease possibly complicated by cholelithiasis. The discovery of gallstones in the stool in addition to the unusual severity of the pain should have made the clinician suspicious of the presence of a cholecystoduodenal fistula. There was nothing in this history suggesting peptic ulcer. Cholecystoduodenal fistula is the most common of the fistulas arising between the biliary tract and the intestines. It is usually caused by the rupture of a stone from the gallbladder into the intestine. This may result after preliminary infection has approximated the walls of the two organs. It is extremely rare for a peptic ulcer to rupture from the duodenum into the gallbladder.

Case 2. Chronic calculous cholecystitis.—A woman, aged fifty years, for five years had had attacks of sharp pain in the right epigastrium, sudden in onset, lasting from half an hour to three hours, and usually relieved by vomiting. The attacks were followed with right infracostal soreness for two or three days. A hypodermic of morphine was necessary on one occasion. These attacks had occurred at intervals varying from one day to one year; however, there had been almost daily mild epigastric distress for five months prior to registration. There had been occasional distress between meals, relieved by eating, and qualitative food distress with much gas and flatulence. There was no history of jaundice or chills and fever.

A Graham-Cole test showed a poorly functioning gallbladder. Gastric acidity was 36 total, and 12 free. The leukocytes numbered 6,200. Fluoroscopic examination of the stomach was negative. At operation the thick-walled gallbladder was found to be buried in a mass of adhesions. Cholecystectomy and appendectomy were performed. When the gallbladder was incised it discharged thick fluid that contained stones and pus. The common bile duct was moderately enlarged and glands along the duct were markedly enlarged. Hepatitis and pancreatitis graded 2 and chronic appendicitis graded 3 were present. The stomach and duodenum were normal.

The history of this case did not include anything which would suggest peptic ulcer; in practically all details it was characteristic of calculous cholecystic disease. The pain of gallstone colic is not as a rule overlooked by the patient in outlining his symptoms. It is usually very severe, and often comes on without warning and frequently stops just as quickly as it began. There is, as a rule, residual soreness in the right upper quadrant of the abdomen. The pain frequently originates in the upper right quadrant and often radiates through to the right scapular area and at times into the neck. It is lancinating and often requires hypodermics for relief. An attack may stop following vomiting. There is often upper abdominal flatulence. Patients observe that their breath seems to be cut off because of intense pain on deep inspiration. In some cases there are only transitory twinges of upper right abdominal pain which, although perhaps severe, are of momentary duration. If the gallstone becomes impacted in the common bile duct, fever, chills, and jaundice are often added to the symptoms of pain. It must be remembered that occasionally a gallbladder packed full of stones does not cause acute pain because the gallstones are so firmly packed that they cannot migrate into the ducts.

Case 3. Acute purulent cholecystitis.—A woman, aged forty-seven years, came to the clinic stating that for six months she had suffered from frequent attacks of dull pain in the epigastrium, which radiated to the back and the right shoulder. The pains had been fairly severe on one occasion, and had required a hypodermic of morphine for relief. There had been soreness and tenderness constantly in the region of the gallbladder. There had been no qualitative food distress, bloating, belching, jaundice or chills. The patient was moderately obese.

General examination revealed some tenderness over the area of the gallbladder, and the edge of the liver was palpable. The Graham-Cole test revealed a poorly functioning gallbladder. The leukocytes numbered 9,900. Cholecystectomy was performed. Acute cholecystitis and one stone blocking the cystic duct were found. The gallbladder was about 5 by 7 cm. in diameter and was full of pus.

In this case the history was again rather clear-cut and the syndrome fairly definitely involved the upper right quadrant. There was constant soreness and tenderness in the area of the gallbladder. There was nothing suggestive of peptic ulcer, and there was no difficulty in making a diagnosis of cholecystic disease.

Case 4. Subacute cholecystitis.—A man, aged forty-nine years, came to the clinic complaining of seven or eight severe attacks of pain in the right upper quadrant for a period of more than two years. The attacks lasted from four to ten hours, and frequently required hypodermics of morphine for relief. There had been residual tenderness of the right costal margin for one or two days previous to admission. There had been no indigestion in the interval, and no jaundice.

A cholecystogram revealed a poorly functioning organ with multiple stones. General examination disclosed rigidity and tenderness in the upper right quadrant. The leukocytes numbered 6,300. At operation the gallbladder was found to be definitely inflamed with marked edema of its walls and contained multiple stones. There was hepatitis graded 2.

It was not difficult to make a diagnosis in this case. Acute or subacute cholecystitis usually causes complaints which are fairly well referred to the right abdominal quadrant. Tenderness and rigidity may be present in the right infracostal area. The gallbladder may be palpable, and tenderness increases as the palpating hand approaches the region in which the gallbladder is usually found. Although the distress may come on periodically it is not unusual to have the complaint of constant distress in the upper right quadrant which is intensified by the ingestion of food, by walking, or by riding in a car. Flatulence and qualitative food relationship are usually noted. The syndrome lacks the precise regularity of that usually seen with uncomplicated ulcer, although at times the distress is intensified several hours after the meal and in this it may have some similarity to ulcer. An icteric tint to the skin is frequently noted in acute or subacute conditions of the gallbladder, and the icterus index or serum bilirubin may be elevated. The urine may be deeply colored, or stools may be light colored. In such cases a study of duodenal content may be of some aid in diagnosis.

Case 5. Chronic duodenal ulcer.—A man, aged fifty-six years, gave a history of stomach trouble of from five to seven years, consisting of spells of distress lasting from two to five years. Between the attacks there were intervals of freedom from symptoms ranging from five months to three years. The pain usually appeared two or three hours after meals, and reached maximal intensity between the noon and evening meals. Relief had been obtained by the ingestion of food, milk or alkalies, but during the last attack the patient vomited three times before relief was obtained. The pain had been gnawing, and was well localized to a small area in the midepigastrium, without radiation until the last attack, at which time severe pain was referred through to the back.

Estimation of gastric content showed slightly elevated acidity but no evidence of retention. Roentgenograms revealed duodenal deformity. A diagnosis was made of duodenal ulcer. At operation a large perforating type of ulcer was found on the anterior wall of the duodenum 5 cm. below the pylorus. The ulcer was about 2 cm. in diameter. Posterior gastro-enterostomy was made. The gallbladder was normal.

This case illustrates the type of syndrome usually found with peptic ulcer. The history of periodicity, and pain coming late after meals, relieved by food and soda, combined to suggest the presence of a peptic lesion, and the recent increase in the severity of the pain, referred into the back, suggested the perforating character of the lesion.

Case 6. Complicated duodenal ulcer.—A man, aged thirty-one years, had been troubled for four years with severe abdominal cramps which awakened him at night. The cramps persisted for a few hours, and left residual epigastric soreness for one week. There was no nausea or vomiting, and roentgen-ray examination at that time was negative. Following the attack he was well for several months. In the autumn of the same year he had attacks of gaseous indigestion that usually lasted for several hours. This distress was relieved by the ingestion of food and soda. There was no epigastric pain. These attacks came on periodically until the following spring, when definite burning pain appeared three or four hours after the ingestion of food. This was relieved by taking soda. Roentgenograms then revealed duodenal ulcer. For three weeks he was in a hospital on a non-surgical ulcer regimen. He did well on ambulatory treatment that consisted of diet and alkalies for about twenty months, when the trouble recurred. The symptoms were again relieved by non-surgical treatment. After further recurrence of the trouble the patient came to the clinic. At that time the symptoms were more severe, the pain which previously had been well localized to a small area in the epigastrium now involved a large area and during the more severe exacerbations radiated through to the back; control by medical treatment was poor, and although there was no frank hemorrhage the material expressed from the stomach during lavage was blood-streaked.

General examination disclosed some epigastric tenderness. A diagnosis of subacute perforating duodenal ulcer was made. This was verified at operation. The ulcer had perforated through the lower border of the duodenum onto the pancreas.

It should be pointed out that subacute types of duodenal ulcer give rise to a syndrome which may simulate that produced by cholecystic disease. In 37 per cent of the cases with surgically verified subacute duodenal ulcer recently reviewed in the clinic, a preoperative diagnosis of associated cholecystic disease was made. The qualitative food relationship of symptoms, the gaseous indigestion, and the localization of pain to the upper right quadrant furnished some suggestions leading to the erroneous impression of disease in the gallbladder, despite the fact that the history included evidence of ulcer, and the roentgenograms gave evidence of a lesion in the duodenum. A carefully taken history with correlation of roentgenologic data, laboratory investigation and gastric analysis usually should furnish sufficient evidence to make the diagnosis of peptic ulcer. If the fact that a subacute or perforating duodenal ulcer may cause an upper right syndrome is borne in mind, an error in diagnosis can often be avoided.

Case 7. Rupture of a gallbladder.—A woman, aged twenty-seven years, had had appendectomy and right salpingo-oöphorectomy twelve years before admission. For several years gas and belching had troubled her shortly after meals. In the last year before admission she had suffered four attacks of severe pain of sudden onset in the right upper quadrant, lasting for about a week. In each instance the pain radiated around the scapula, and was associated with vomiting. Hypodermics of morphine were necessary to relieve the pain. The second attack was mild; the third and fourth attacks were severe. In the last attack jaundice appeared.

Marked abdominal tenderness over the right upper quadrant was noted. Masses could not be palpated. The skin had an icteric tint. The temperature was normal. The urine showed a trace of bile, and a few erythrocytes and pus cells. Leukocytes numbered 5,800. The serum bilirubin was somewhat elevated. The blood coagulation factors were normal. Operation disclosed a ruptured gallbladder, an abscess at the base of the cystic notch with multiple stones, and a stone in the common bile duct. The stomach and duodenum were normal. Cholecystectomy was performed. The pathologists reported subacute cholecystitis with perforation, and multiple stones.

In this case a preliminary history suggestive of disease of the gallbladder was present for at least a year prior to the time when rupture of the gallbladder occurred. There had been several attacks of severe pain in the right upper quadrant radiating through to the scapula. The onset of this pain was sudden and presented the characteristics often seen in cases of gallstones. The last attack had been severe and there was definite localizing evidence of peritoneal irritation in the right upper quadrant. The history of the case definitely incriminated the gallbladder as the cause of the symptoms. A complication of some type should have been suspected.

Case 8. Acute perforation of duodenal ulcer.—A man, aged twenty-six years, had had occasional mild upper abdominal distress for two years, which usually came on two hours after meals; this was relieved by food or soda. Four months before admission he had had a severe attack of epigastric distress lasting a week. Three weeks before admission he had suffered a similar, although less severe, attack. One day while he was leaning over washing windows, he was seized with a sudden acute abdominal pain. He was brought to the clinic and placed in hospital.

The breathing was chiefly costal. The patient's slightest motion seemed to intensify the pain. The respiratory rate was increasing; the pulse rate was normal. There was board-like rigidity of the abdomen and exquisite abdominal tenderness. The point of greatest pain was slightly above the umbilicus. Visible peristalsis was absent. Leukocytes numbered 11,500. A diagnosis of ruptured peptic ulcer was made. Operation, about two hours after the onset of severe pain, disclosed an acutely perforated ulcer on the anterior surface of the duodenum. The perforation was closed.

In this case the symptoms were characteristic of ulcer for several years before rupture took place. Symptoms of disease of the gallbladder rarely simulates symptoms of ruptured ulcer, although occasionally an acutely infected gallbladder will rupture and the resulting peritonitis may cause a mistaken diagnosis. Rupture of the gallbladder, however, except following trauma, is almost invariably a late development in cholecystitis and a carefully taken history should, as it did in this case, present evidence to aid in making the diagnosis. Acute cholecystitis with rupture of the gallbladder is most common in women, and ruptured ulcer almost always occurs in men. We have been told that perforation of ulcer is not infrequently the first sign of such a lesion. It should be pointed out that perforation almost invariably is preceded by a syndrome of indigestion with definite characteristics of ulcer.

Case 9. Chronic calculous cholecystitis.—A woman, aged forty-seven years, had experienced much gas and belching and abdominal distention for fifteen years. The distress usually came on shortly after meals. At times she had noticed slight cramping pains in the epigastrium. These were of short duration, occurring two, three, or four times a week. Often she experienced distressing epigastric fullness at night. There was definite qualitative food distress, fried greasy food causing the most distress. She frequently had vomited.

The Graham-Cole test revealed a poorly functioning gallbladder. The abdomen was tender to the right of the umbilicus and sensitive over the entire right side. At operation chronic cholecystitis with cholelithiasis was found. The stomach, duodenum, pancreas and ducts were normal.

This case illustrates that the diagnosis of chronic cholecystic disease, even though stones are present, may be extremely difficult. If pain is not distinctly referred to the upper right quadrant, if there is no cramping or colicky exacerbation, and only symptoms of qualitative food relationship, burning and vomiting, the diagnosis may be exceedingly perplexing. The cholecystogram has been of unquestionable value in helping to detect cholecystic disease in such cases. In some cases it would be impossible to make a preoperative diagnosis except through cholecystographic investigation. The so-called reflex to the gallbladder as a cause of indigestion is extremely indefinite. Many of these syndromes have been outlined as being diagnostic of disease of the gallbladder. They may include indefinite epigastric discomfort following meals, flatulence, nausea, vomiting, belching, and bloating after certain types of foods such as onions or apples. We have not found such syndromes reliable in indicating cholecystic disease. Functional disturbances of the upper part of the digestive tract, constipation, and food allergies are likely to give similar syndomes. There should be some hesitancy in assuming that the gallbladder is the cause of such syndromes unless the previous history includes some localized evidence of more severe or more definite disease in the upper right quadrant.

Case 10. Perforating duodenal ulcer with right upper quadrant pain.—A man, aged thirty-five years, stated that for seven years he had had attacks of pain in the right upper quadrant of the abdomen coming in "spells" lasting several days, at the onset occurring three times a year with free intervals, but just prior to admission, twice monthly. The pain was severe, beginning under the right costal margin and radiating along the right costal margin to the back. One year after the onset the appendix was removed and the gallbladder drained without relief. Finally, six months prior to examination at the clinic a diagnosis of gastric ulcer had been made. A diet and alkali powders relieved the pain until two weeks before admission, when the patient noticed that these measures were inadequate. The pain was quite severe and now began to radiate through to the back. Hypodermics of morphine were given. On one occasion blood had been vomited.

There was slight tenderness under the right costal margin and over the right lower quadrant. Masses were not palpable and there was no rigidity. The urine was normal, the leukocytes numbered 9,500, the Wassermann reaction of the blood was negative, and the gastric acids were 90 for total and 70 for free hydrochloric acid. Roentgen-ray examination of the gallbladder according to the Graham-Cole method showed a normally functioning organ. The fluoroscope revealed duodenal deformity. At operation an ulcer of the subacute perforating type was found on the anterior surface of the duodenum below the pylorus. There were no stones in the gallbladder. Posterior gastro-enterostomy was performed.

This case illustrates the fact that subacute perforating duodenal ulcer may produce a syndrome closely simulating that caused by cholecystic disease. The pain and distress may be entirely in the upper right quadrant. There is, however, usually something included in the history, such as food ease, soda ease, or distress, reaching maximal intensity several hours after the meal, which suggests a peptic lesion. If the history includes hemorrhage, such as was noted in this case, the diagnosis is made more easily; otherwise roentgen-ray data may be the determining factor.

Case 11. Duodenitis and a history suggesting a lesion of the gallbladder.—A woman, aged forty-five years, complained of having had stomach trouble for ten years. Attacks lasted two or three weeks and occurred two or three times a year. The distress ranged from mild to definite pain in the midepigastrium and occasionally this was referred to the back. The distress came on from half to one or two hours after meals, always with much gas. It usually followed the ingestion of fried greasy food. There had been no jaundice, no colic, and no vomiting. Soda and food occasionally relieved the distress.

The systolic blood pressure was 120 and the diastolic 70 in millimeters of mercury. There was slight tenderness in the right upper quadrant. The urine was normal, leukocytes numbered 7,700, and the gastric analysis gave total acidity 48 and free hydrochloric acid 34; the total quantity aspirated was 120 c.c. Roentgenograms of the stomach were negative. A diagnosis of chronic cholecystitis was made. At operation a normal gallbladder and a normal-appearing liver were found. The stomach was somewhat thickened and dilated. Diffuse duodenitis was noted, and the pylorus was found to be hard, firm and sclerosed. Pyloroplasty and appendectomy were performed. The pathologists reported duodenitis and chronic catarrhal appendicitis. Convalescence was without incidence and thus far the patient has remained well.

This case demonstrated that duodenitis may closely simulate a syndrome caused by cholecystic disease. Usually, however, there are certain characteristics, such as food ease, soda ease, periodicity or distress coming late after meals, which offers some assistance in diagnosis. A recent review in the clinic of a large series of surgically verified cases of duodenitis suggests that duodenitis, even if unassociated with ulcer, can be a formidable lesion of definite clinical significance.

SUMMARY

Complicated cholecystic disease usually is productive of a syndrome which so definitely focuses attention to the region of the gallbladder that diagnosis is made without difficulty.

Subacute duodenal ulcer, duodenitis, or subacute perforating duodenal ulcer frequently produces a syndrome which may simulate that caused by disease of the gallbladder. The pain may be in the right upper quadrant, referred upward over the region of the liver, and there may be associated flatulence and qualitative food distress. The history, however, usually includes sufficient characteristics of ulcer, such as distress late after meals, food ease, soda ease, and periodicity, to make diagnosis possible.

In a review of a history it is important to obtain information regarding the present attacks of dyspepsia and to compare these with previous gastro-intestinal exacerbations.

By the judicious evaluation of data obtainable throughout the history of the case, roentgenologic investigations, and the laboratory aids such as icterus index, serum bilirubin, and occasionally studies of duodenal contents, the differential diagnosis of cholecystic disease and duodenal ulcer usually is possible.

CONCERNING LIMITATIONS OF THE CLINICAL SIGNIFICANCE OF LOW BASAL METABOLIC RATES*

C. A. McKinlay, M.D.
Minneapolis

ALTHOUGH, with the advent of simplified methods, clinical calorimetry has become a common procedure, its value in diagnosis and as an indication for therapy is proportional to an appreciation of all the factors that influence the energy exchange of the body. Recent reports by Thurmon and Thompson,[5] and Remington and Culp,[4] tend to show low basal metabolic rates are not uncommon in individuals who are apparently normal or who have only minimal functional disturbances without myxedema. A preliminary report of a study of a group of young adults which shows similar results is included in this paper.

On the other hand the clinical significance of increased heat production is usually clear, as the diseases (other than hyperthyroidism) that have increased basal metabolism by their nature are not usually confusing; for instance, leukemia, polycythemia and acromegaly are not common and have, of course, other and better diagnostic criteria. In addition, pyrexia should be kept in mind for, in almost all infections, increases of basal metabolism of approximately 7 per cent per degree F. occur.

While the usually accepted range of normal variability is within plus or minus 10 per cent, it should be mentioned that the Aub-DuBois standards in common use are approximately 4 or more too high according to Krogh.[3] Myxedema, with rates from minus 25 to minus 40, is usually outspoken in its manifestations and need not be considered here. The glandular dyscrasias other than myxedema or Fröhlich's syndrome and other hypopituitary states and Addison's disease are not common, and have outstanding physical characteristics; all may have a reduced metabolism. However, the establishment of a diagnosis of hypothyroidism without myxedema requires careful study of each individual case beyond obtaining a laboratory report of a basal metabolism of from minus 15 to minus 25 per cent. The interpretation must include consideration of other conditions, aside from diminished thyroid function, that are associated with lower metabolism. Benedict[4] showed that the basal metabolism in a starving individual fell 30 per cent, and that[2] in a group of young men on a low caloric diet (approximately 1,400 calories for three weeks) the basal metabolism fell 18 per cent. This reduction is probably due to a protective mechanism on the part of the body, not, however, a primary thyroid influence. While starvation is rare, the physician frequently sees under-nourished individuals who, for various causes, at times imaginary, have restricted their diet to a point of caloric deficiency. Although in under-nutrition thyroid deficiency is not primarily present, if the condition is of such long standing that there may be secondary alteration of thyroid function, the use of thyroid extract has been suggested in treatment in combination with increased food intake.

Since muscular inactivity tends to depress the basal metabolism it should be remembered that in invalidism, as in certain anemias and arthritic conditions with long periods of inactivity, there may exist secondary lowering of basal metabolism.

Keeping in mind, then, that physiologic and pathologic states, other than a primary change of thyroid function, tend to depress the basal metabolism of the body, the physician will be in a position to evaluate a reduced basal metabolism in individuals without myxedema. It presupposes that a complete study of the case has been made, that chronic infection, including tuberculosis, and anemias or other chronic states with invalidism have been excluded or evaluated and that there is no demonstrable cause of symptoms.[6] After exercising such caution, there remains a group of cases with fatigue, exhaustion, low energy level, anemia, unexplained dizziness, sensitivity to cold, drowsiness, obesity without overeating, sterility and menstrual disorders, in which the therapeutic trial of thyroid extract is justified even though physical signs in the form of skin and hair changes are minimal or not demonstrable. While a number of these individuals may respond well to treatment, there will be differentiated by this therapeutic test the group without improvement and presumably without any thyroid deficiency. This group is worthy of further study. Undoubtedly some of them have a nutritional deficit sometimes on an infectious basis which has not been evaluated. Although under-nutrition itself tends to depress basal metabolism, it is somewhat paradoxical that under-nutrition may be, and often is, due in some degree to the high rate of energy exchange characteristic of hyperthyroidism. In obesity, normal values usually obtain although there is a tendency for some individual cases to have low basal metabolism.

---

*Presented before the Hennepin County Medical Society, February 18, 1931.

Some of the group with low basal metabolism appear to be entirely normal. Is their low metabolism comparable to the physiologic slow pulse, low temperature and low blood pressure of certain individuals? In such individuals studied after the development of some complaint, the normality of a low basal rate for the individual should be kept in mind. Whether some of this group will later develop hypothyroidism or myxedema is a question. Against this, evidence exists that hyperthyroidism is a precursor of myxedema in a certain percentage of cases where hyperfunction of the gland leads later to retarded or absent activity.

A study is being made of a group of individuals without marked physical defects. Determination of the basal metabolic rate was made often on account of rather minor non-capacitating disturbances of function, as overweight, underweight, menstrual disturbances and fatigue, and also on account of colloid goiter. None had myxedema. Multiple determinations made on a group of 155 students, aged 17 to 35, at the University of Minnesota, are referred to. The Roth-Benedict apparatus was used in 134; the McKesson in 20; usual standard basal conditions were obtained and Aud-DuBois standards were used.

It is seen that over one-fourth of this group had low basal metabolic rates. While in some of these under-function of the thyroid may be present as indicated by response to substitution therapy, in many others no such under-function was established. A study is being made of this group, in order that the proportion of normal individuals may be established from the results of complete routine examination.

In conclusion, the increased clinical use of the determination of basal metabolism makes imperative a critical attitude in its interpretation as a diagnostic aid. It must be kept in mind that under-nutrition and inactivity tend to depress the basal metabolism and that certain apparently normal individuals have the basal metabolism below normal limits according to standards and procedure in common clinical use. The findings in a group of 155 young adults with good working capacitty show that in 27.9 per cent the basal metabolic rates were below normal.

THE ADHESIVE BANDAGE IN TREATMENT OF VARICOSE ULCER*

CLAUDE F. DIXON, M.D., and FREDERICK L. SMITH, M.D.
Rochester, Minnesota

THE injection treatment of varicose veins has become established. Application of an adesive bandage, combined with injection, or aplication of an adhesive bandage only, is proving fficacious in the treatment of varicose ulcers, hich are the most common ulcers of the lower xtremity. By directing attention to those ulcers f the lower extremity which are associated with rteriovenous fistula, it may be seen why the use f an adhesive bandage would be of value in the eatment of varicose ulcers. In order that oxyn may be properly distributed to the extrem, the blood must pass through the capillaries fore reaching the venous system. In the arriovenous fistula the blood does not pass rough the capillaries but is emptied directly om the artery into the vein. Consequently, and gically, ulcers which develop in connection with arteriovenous fistulas of the lower extremity occur below the arteriovenous opening. If a tight bandage is applied in such a case so that the vein at the point of the fistula is compressed and blood is forced to pass through the capillaries, healing rapidly follows. Recurrence eventuates if the bandage is discarded for any length of time.

In varicose ulcers of the lower extremities conditions as follows are often present:

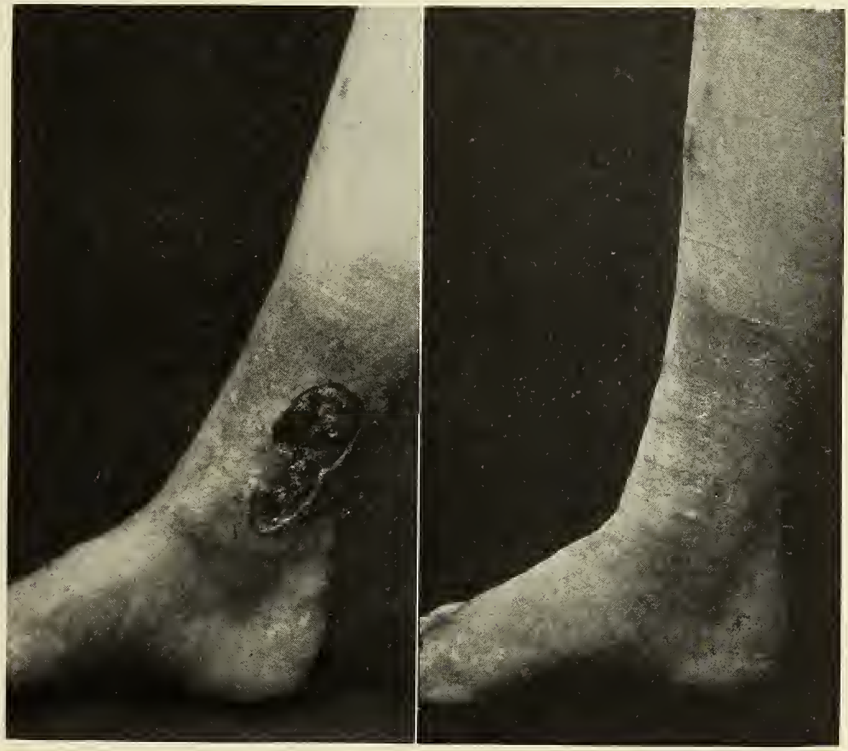

Fig. 1. Before treatment.

Fig. 2. After treatment.

Group 1.—Huge, tortuous veins which have permitted slowing, complete stoppage, or even reverse flow of blood, cause improper oxygenation, as in the arteriovenous fistula, and ulcer results in many instances. If a tight bandage is applied or the veins are injected in this type of case, healing results because the stagnant pool of poorly aerated blood has been eliminated and circulation has been formed through the capillaries. In this particular group if the ulcers are large and markedly infected, we suggest bandaging for two or three weeks, after which partial or complete healing will have taken place and the infection and edema will have definitely decreased. Injection of the veins may then be carried out with complete and permanent healing of the ulcer.

---

*Submitted for publication May 5, 1931.

Group 2.—Much the same condition exists in these cases as in those of Group 1 except that the tortuous or obstructed veins are in the muscles and therefore are not visible and, in many instances, not palpable. In this type of case, obviously, treatment of the ulcer may be carried out by means of bandaging alone. Occasionally, after the ulcer has healed and the bandage is discarded, premonitory symptoms of recurrence appear, such as eczema, cyanosis, and edema. Bandaging again should be resorted to, and at irregular intervals, as indicated.

The use of Unna's paste casts have been of much value in the treatment of varicose ulcers. Any compression bandage is of benefit in the treatment of this condition. The difficulty with the bandages used heretofore has been that they did not remain snug; thus recurrence of the engorgement of the tortuous veins was permitted and the purpose of the bandage more or less defeated.

The two cases presented at the end of this paper illustrate each of the two groups of varicose ulcers and the results obtained following the use of an elastic, adhesive bandage. In case 1 the bandage was supplemented by injection. In case 2 the bandage only was employed.

The elastic, adhesive bandage may be applied directly over the ulcer or a piece of plain gauze may be placed over the ulcer before the bandage is applied. It is well not to change the bandage for several weeks, particularly if the ulcers are large, unless the patient experiences discomfort, which is rare. However, a new bandage may be applied every week or two without hindrance to healing. If the limb is markedly swollen, the first bandage should be applied when the swelling is at a minimum; for example, in the morning. Discomfort may be experienced for an hour or two, after which comfort and freedom from symptoms are the rule. In huge ulcers it is obvious that several weeks may be required for complete healing.

A skin graft, followed by the immediate application of a bandage on an ambulatory patient, has been of considerable value. The graft is applied as follows: Five or six small strips of skin, 1 to 2 mm. wide and 10 or 12 cm. long, are taken from the thigh. By the aid of a fascia needle these threads of skin are sewed into the ulcer in lattice fashion, without care or caution as to the position of the epithelial surface. This method can readily be carried out in an office under local anesthesia. In order to obtain a good result the graft must be used on a granulating surface.

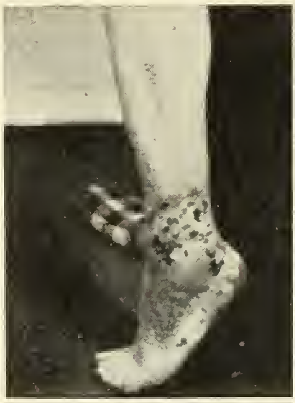

Fig. 3. Before treatment.

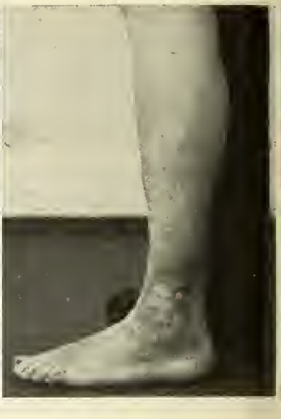

Fig. 4. After wearing bandage nine days.

REPORT OF CASES

Case 1.—A woman, aged fifty-four years, had a large varicose ulcer on the inner aspect of the right leg. There were several medium-sized, tortuous veins over the posterior aspect of the leg. An elastic, adhesive bandage was applied over the entire extremity. The bandage was replaced three times during a period of eight weeks, at the end of which time the ulcer had healed completely. Four injections of quinine dihydrochloride and urethane (dose 2 c.c.) were given after completion of the bandaging treatment (Figs. 1 and 2).

Case 2.—A man, aged forty-four years, had had multiple ulcers over the outer aspect of the lower part of the left leg and ankle for six months. During the last three weeks retraction of the heel and pain had made it necessary for him to resort to crutches. An elastic, adhesive bandage was applied over the foot and lower part of the leg. Relief of pain was experienced in a few hours and he could walk comfortably without the use of crutches in five days. The bandage was removed in nine days, at which time the ulcers were completely healed (Figs. 3 and 4).

RETROCECAL APPENDICITIS*

Herbert Busher, M.D.
St. Paul

IF the appendix lies behind the cecum, and is consequently hidden from view upon opening the abdomen, it is called a retrocecal appendix. Such an appendix was found in 17 per cent of all appendectomies at the Boston City Hospital, and in 25 per cent at the Johns Hopkins Hospital, according to their recent reports. It occurred twice as often among men as among women. It was adherent and kinked twice as frequently as the normally situated appendix. The mesoappendix was usually shorter than normal, and sometimes entirely lacking. In the latter case, the appendix lay beneath the peritoneum of the cecum, commonly between the cecum or ascendng colon and the psoas muscle which forms the posterior abdominal wall at this point. An appendix so located is retroperitoneal as well as retrocecal, and occurred thus in 2 per cent of all cases reported in these statistics. Most of the appendices "not found" are of this sort. Frequently an originally free retrocecal appendix may be so concealed by an adherent cecum that t will be erroneously considered to be retroperioneal. A retrocecal appendix may be straight, kinked, or curled up. It may point directly upward, or to one or the other side.

The reason for the frequent occurrence of a retrocecal location of the appendix lies in the atter's embryological history. In a very early mbryo the primitive gut is a straight little tube of even caliber. It soon outgrows the capacity of he abdominal cavity and forms a loop which extends part way into the umbilical cord, suspended by a long mesentery. When, in the third etal month, the gut returns into the abdomen, t can crowd in only by forming numerous maller loops. The lower portion, destined to beome the colon, now forms a semilunar loop, omewhat larger than the many smaller loops of he upper portion representing the small intestine. This colonic loop then rotates around the small ntestine in a counter-clockwise manner, carryng with it its mesentery like an opened fan. In he fourth month the primitive cecum lies in the upper right abdomen under the liver. From then on until birth there occurs a gradual descent of the cecum into the iliac fossa. During this time the lower end of the cecum lags in growth and becomes the appendix. Also during this period of descent, the mesentery of the cecum and colon becomes adherent and fuses with the parietal peritoneum of the abdominal wall behind it. Thus it happens that the posterior wall of the cecum descends more slowly than the free and unhampered anterior wall, and a certain amount of curling backward of the cecum is quite the usual thing. It is surprising, therefore, that not every appendix is retrocecal. If, as occasionally happens, the tip of the appendix becomes adherent to the posterior abdominal wall in the region of the right kidney, as the cecum descends, a true extraperitoneal appendix is the result.

Acute inflammation is relatively more common among retrocecal appendices than among those normally situated. Especially true is this where the appendix is actually retroperitoneal. Aschoff states that the retrocecal position makes emptying of the appendix difficult, and at the same time makes obstruction of the blood supply easy, because of the bend that is present, opposite to the general direction of peristalsis and circulation. And for this reason inflammation and gangrene are common. Howard Kelly thinks that in cases of retroperitoneal appendices the friction against the psoas muscle in walking may cause an irritation not experienced by a free appendix. Small found perinephritic and subphrenic abscesses more prevalent in cases of appendicitis of the retrocecal variety. This seems logical when one considers the close proximity of the right kidney and the looseness of the connective tissue behind the peritoneum in that vicinity. On the other hand Quain and Waldschmidt, reporting a thousand cases of appendicitis, found the retrocecal type less dangerous than the average, for the simple reason that the retrocecal appendix lies in an out-of-the-way corner as far as the general peritoneal cavity and its contained viscera are concerned, where it can more quickly and more easily be walled off.

---

*Read before the Ramsey County Medical Society, St. Paul, April 27, 1931.

The clinical picture of retrocecal appendicitis is unusual only in that small percentage of cases where the appendix is not free and pendulous but is either retroperitoneal or enclosed in a pocket behind a posteriorly adherent cecum. However, in these few instances we encounter symptoms out of the ordinary. On the one hand, as Behan has pointed out, the peritoneal irritation of the sympathetic nerves is minimal. Hence, the midabdominal or epigastric ache, accompanied by nausea and vomiting, is not as prominent as it is in an ordinary attack of appendicitis, and may even be absent in a frank retroperitoneal case. On the other hand, the irritation of the sensory nerves of the abdominal wall takes place more promptly. Local pain and tenderness, and muscular rigidity, therefore, become early symptoms; in fact, they frequently are the first to appear. Their location also is different from that in ordinary appendicitis. Due to a higher and more posterior nerve irritation the pain, tenderness on pressure, and muscle rigidity are found more commonly in the flank or lumbar region rather than in the lower right quadrant. And to confuse the picture still more there exists a tendency for the pain to radiate toward the inguinal region, a circumstance which Mackenzie explains upon the basis of the radiation of the nerve fibers which supply the region of the kidney and ureter. Bruno Cohn draws our attention to a symptom quite characteristic of a retrocecal retroperitoneal appendicitis, due to an irritation of the psoas muscle. The patient will lie with the right thigh flexed in order to favor the psoas, and an attempt to extend the thigh causes increased pain. If a case progresses to abscess formation, the dullness and resistance to pressure are located more commonly in the flank between the rib margin and the iliac crest. Farther anteriorly the gas filled cecum and colon will overlie the abscess and tympany on percussion is more often found than dullness.

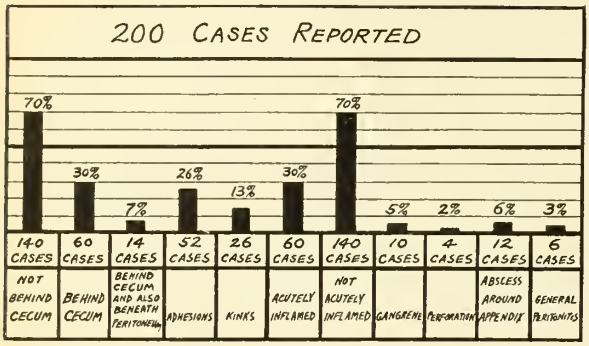

Fig. 1.

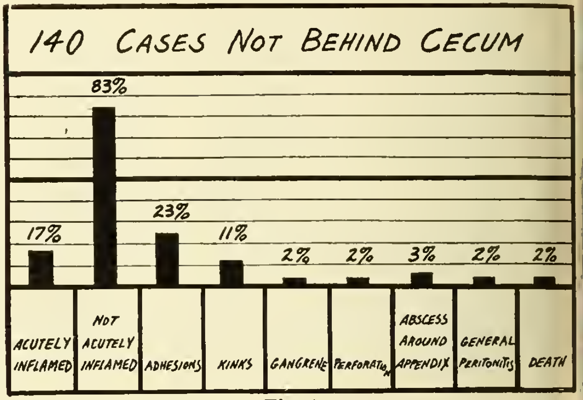

Fig. 2.

From a practical standpoint the most important question about retrocecal appendicitis is that of differential diagnosis. Occasionally the possibility of a gallbladder disease may enter into the picture. Close analysis of the previous history, and the radiation of the pain, together with Graham-Cole cholecystography if time permits, will usually clear up the uncertainty. More frequently we must differentiate retrocecal appendicitis from right urinary disease, particularly from acute pyelitis. Especially now, when our attention is drawn constantly to the numerous unnecessary appendectomy scars in cases of right urinary trouble, we must beware of the rare but real possibility of making the opposite blunder of mistaking a retrocecal appendicitis for a pyelitis. Guy Hunner emphasized this danger when he reported cases in which inflamed appendices lay behind the ascending colon and near the ureter. In these cases he found lumbar pain radiating into the groin and thigh, accompanied by frequent and burning urination, and found blood and pus in the urine. Such symptoms are undoubtedly very misleading. In discussing the diagnosis of these cases, H. W. Carson brings out a few differences which should be kept in mind. Acute pyelitis usually begins with chills followed by high fever, both of which symptoms are very unusual in early appendicitis. Another distinguishing point is the contrast between the subjective pain and the objective tenderness. In pyelitis the patient complains of great pain but is not very tender on pressure, whereas in retrocecal ppendicitis the pain is only moderate while the enderness is great. With this greater tenderness goes a muscular rigidity which is rarely found n pyelitis. Of course, if time permits, pyelography and intestinal radiography may simplify he problem. However, if, after a careful study, here still exists an honest uncertainty, it is wisest o operate, in view of the possible greater danger f an overlooked retrocecal appendicitis.

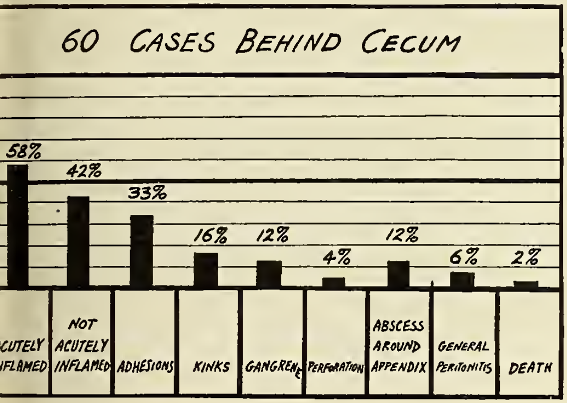

Fig. 3.

I wish to present an analysis of the anatomical nd pathological findings in two hundred consecutive appendectomies. This series includes ses operated upon primarily for disease of the ppendix, and also cases in which the appendix as removed secondarily in the course of operaons for other abdominal conditions. For the ke of brevity and clarity I will present this alysis in the form of graphs, to be thrown n the screen.

SUMMARY

1. In 200 consecutive appendectomies a retrocal position of the appendix was found in 30 r cent of the cases, and a retroperitoneal as ell as retrocecal position was found in 7 per nt of the cases.

2. Acute inflammation of the appendix was und to be three times as frequent among the trocecal group and five times as frequent in the retroperitoneal group as in those normally situated.

3. The retrocecal position of the appendix was found three times as frequent among the cases of acutely inflamed appendix as among the non-acute, and the retroperitoneal position was found seven times as frequent among the acute cases as among the non-acute.

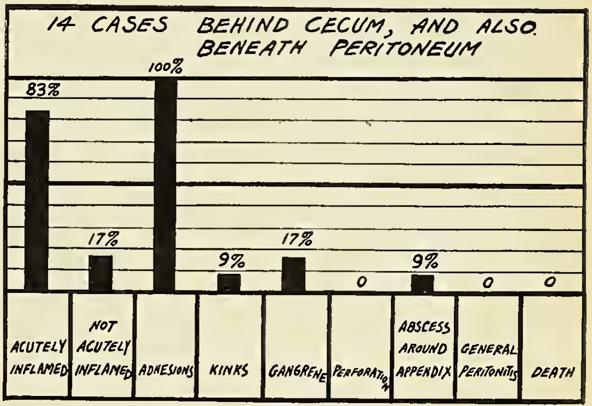

Fig. 4.

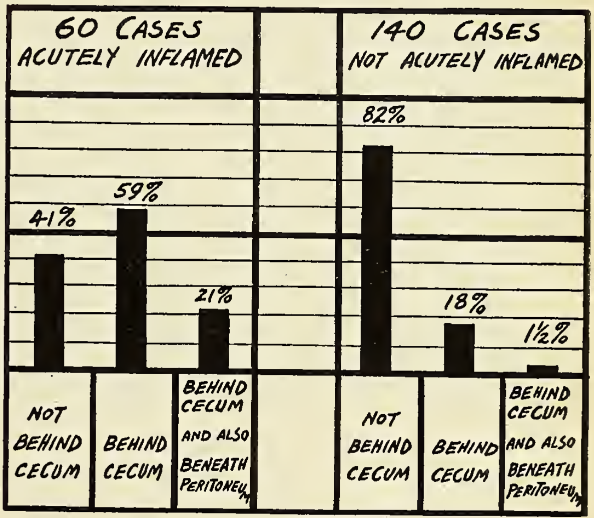

Fig. 5.

Conclusion.—A retrocecal position of the appendix, especially when it is also retroperitoneal, is an important factor causing the appendix to be susceptible to acute inflammation.

COMPRESSION FRACTURES OF THE VERTEBRÆ

M. H. Tibbetts, M.D., F.A.C.S.
Duluth

In order clearly to distinguish between a compression and a comminuted fracture we may define the former as a crushing injury which results in a lessening of the vertical height of the body. Most of this occurs at the anterior portion of the bone and forms a so-called "wedge deformity." As a rule, the posterior area remains intact and offers a point of leverage to be utilized in treatment. This will be alluded to subsequently. This fracture is really a telescoping of a portion of the body as contrasted with dissolution of the vertebra into several fragments, unimpacted, as seen in the comminuted fractures.

The compression fracture is usually brought about by a "jack-knifing" or acute flexing of the spine. The resilient intervertebral discs are unable to absorb all of the force and the trabeculæ of the bone telescope with each other. Falls of varying heights may be the immediately inciting cause. Even being thrust into a sitting position unexpectedly has resulted in a compression. Auto collisions are increasingly responsible for some of these lesions. The mechanism here is again acute flexion—probably with feet braced and body thrown forward by the sudden impact. Some are due to direct crushing blows, as in cave-ins in a mine or a falling roof.

Regarding sex, women are appearing more frequently in the list with the increasing use of the automobile. Before this, males predominated, owing to their more frequent exposure to hazards in line of their occupations. Adults seem to have a corner on the malady, and adults past middle life subjected to the same hazards are much the more susceptible.

There are no pathognomonic symptoms. They are simply those resulting from any acute injury and are pain on attempted motion, tenderness on direct pressure over the lesion, and increasing pain in the sitting or upright position.

The most serious complication is, of course, varying degrees of injury to the spinal cord, from slight edema to complete severance. Regarding the next point, I am not entirely convinced as to whether it should be listed as a complication or a symptom. Indeed, it has appeared so uniformly in my own series of cases that I have almost concluded that it must be a constant factor. I refer to the distressing abdominal distention. It is painful and most resistant to remedial attempts.

Roentgenographs taken in the anteroposterior and lateral views clinch the diagnosis. Unfortunately, they are too frequently omitted and too many of these lesions go unrecognized. Wallace[4] goes so far as to state that 50 per cent are not discovered until secondary symptoms cause increasing disability, and increasing deformity impels the attending physician to seek roentgenologic evidence.

As will be shown later, inasmuch as with early treatment practically normal restoration of the form of the vertebra can be accomplished, a strong plea is here made for more careful search for these lesions. The lateral X-ray view is all-important, and if taken more frequently fewer disabling backs will come up for compensation adjustment.

Tuberculosis of the spine in its typical form simulates the wedge deformity so closely that superficial scrutiny may confuse the two. The tuberculous lesion usually causes destruction of the intervertebral disc not seen in fractures. In general, it causes much more atrophy of the body along with actual destruction and there is usually evidence of abscess formation.

Rickets, giving rise to a rounded adolescent kyphosis, usually results in wedge shaped vertebra, but these are most frequently multiple and show no widening of the body as is frequent in fracture.

The wedging seen in osteoarthritic spines and the collapse of a carcinoma metastasis must be kept in mind. The former offers real difficulty especially if there is a history of injury. Unless seen soon after the accident, when definite evidence of fracture can be seen, differentiation is often impossible.

TREATMENT

We come now to the main point of this presentation—the treatment.

---

*From the Duluth Clinic.

It is only within the last few years that much has been said or written regarding the correcion of these deformed vertebræ. Davis[1] of Erie, Pennsylvania, has furnished an excellent bibliogaphy, citing some seventy-five different articles. He described a method by which these crushed ones could be restored to practically their orignal shape. The basis of his treatment is dependnt upon hyperextension of the spine. The lateral rticular processes, the posterior portion of the ody of the vertebra and the lateral masses, contitute a fulcrum by which the crushed vertebra s pulled apart. The strong anterior ligament of he spine prevents too great an extension and also cts as a limiting membrane, according to Davis, which helps in splinting the crushed fragments nd in holding them in place.

The method used by Davis is to anesthetize the atient, place him prone upon a table, and then with traction on the feet lift the pelvis entirely free from the table. While in this position gentle manipulation is performed at the site of the deformity, pressing downward on the deformed vertebra to bring it back into its proper alignment. After this a long posterior plaster shell is applied, the patient then turned on his back after the plaster has sufficiently hardened, and an anterior shell (holding the spine in hyperextension) applied.

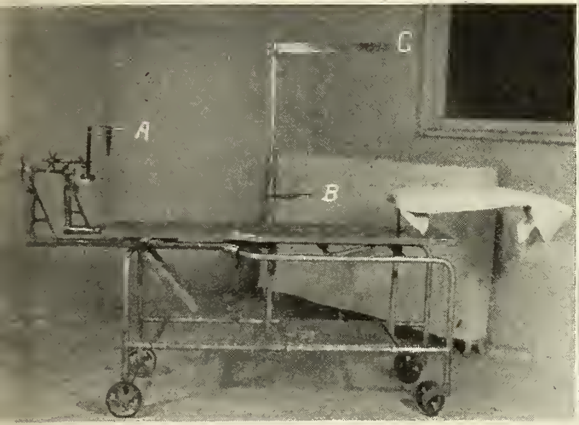

Fig. 1. The Hawley table. (A) Foot attachments for counter-traction; (B) Sacral rest; (C) Overhead bars.

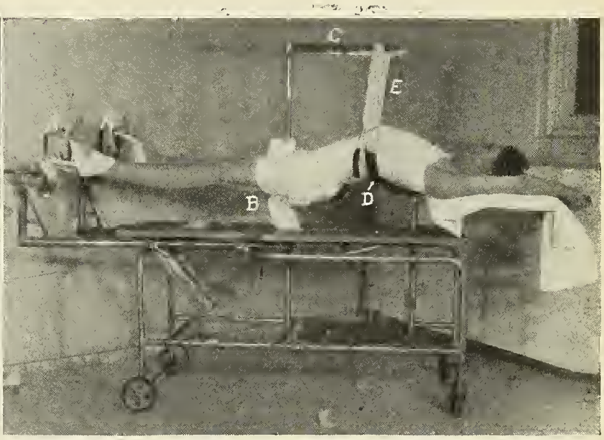

Fig. 2. Patient on Hawley table, showing: (A) Foot attachments; (B) Sacral rest; (C) Overhead bars; (E) Muslin bandage lifting spine into hyperextension; (D) Heavy saddle felt to protect against pressure.

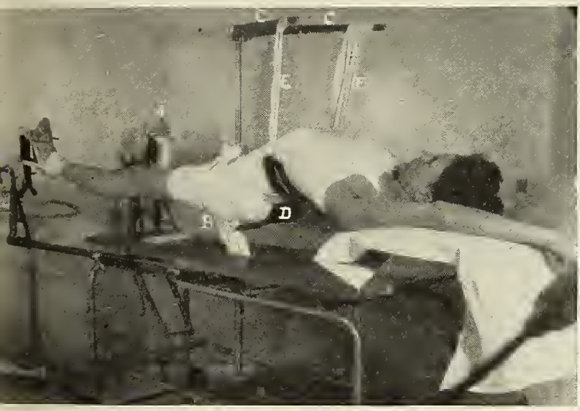

Fig. 3. Same as Figure 2 from a different angle.

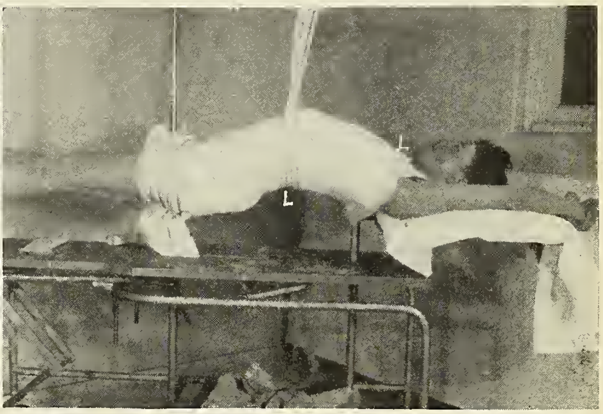

Fig. 4. Showing the points of leverage to maintain hyperextension.

Dunlop and Parker[2] of Pasadena, California, later described a manipulation to accomplish the same thing, which they developed entirely independent of Dr. Davis' method. Their procedure requires five assistants besides the operator: two men hold the feet, two others hold the upper end of the patient by a sheet folded and passed under the chest and arms, while the operator and his assistant hold a folded sheet under the site of the fracture, the patient first being thoroughly anesthetized and laid on his back. Then the four men (two at the head and two at the feet) throw the patient upward, exerting strong traction all of the time, and then allow the body to drop down and be caught by the operator and his assistant, care being taken to keep the spine in the hyperextended position during this maneuver. The jerking thus obtained presumably dislodges the impacted fragments and allows the vertebra to assume its normal position through hyperextension. After this manipulation a plaster cast is applied with the back in the hyperextended position.

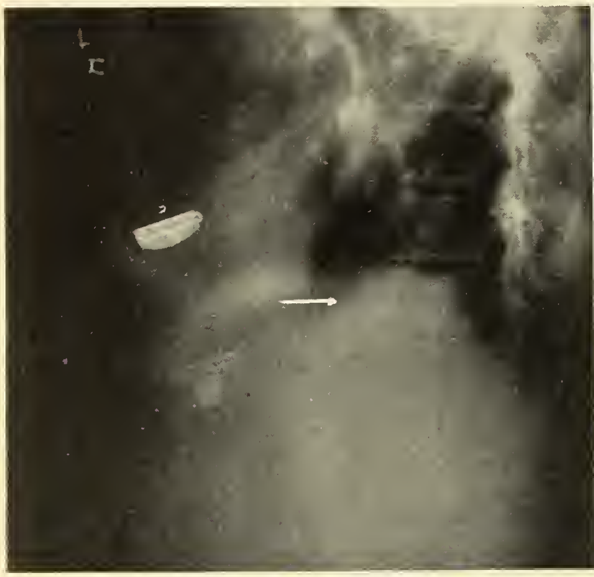

Fig. 5. Case 1. X-ray before reduction, showing compression of eleventh thoracic vertebra.

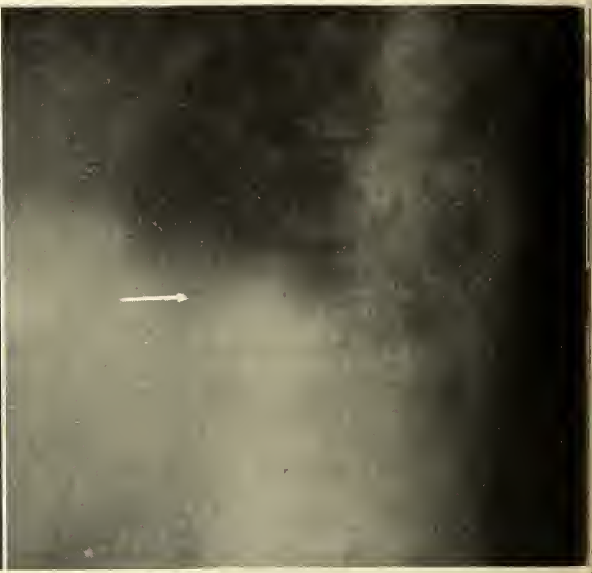

Fig. 6. Case 1. X-ray after reduction. Note restoration of anterior border of eleventh thoracic vertebra.

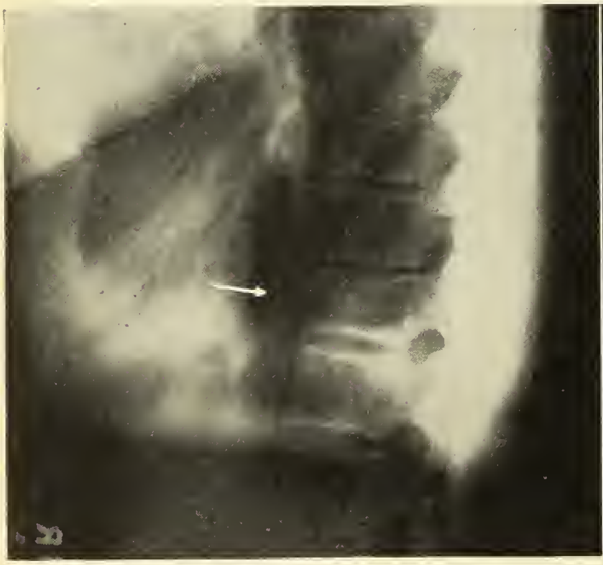

Fig. 7. Case 1. X-ray nine months after Figure 5. Bony restoration of trabeculæ.

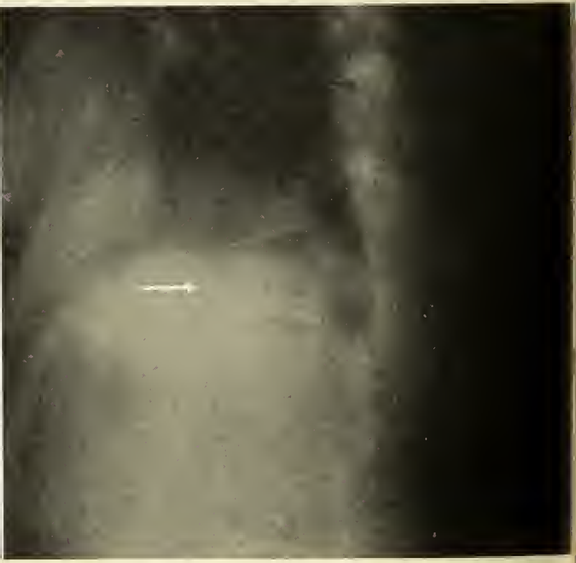

Fig. 8. Case 2. X-ray before reduction. Compression twelfth thoracic vertebra.

Still another procedure has been described by Rogers[3] of Boston, which does not require the patient to be anesthetized, and the manipulatio is carried out over a period of several days, usin a frame similar to a Bradford frame. The difference in this particular frame is that the latera bars are made of flat spring steel rather than round tubes. The lateral bars being made of spring steel will thus bend into a convex or a concave position, but will not bend toward each other. The patient is placed upon the frame and the frame is then made convex gradually over a period of several days until the required amount of hyperextension is obtained. The patient remains on this frame for several weeks. The contribution which I am offering is that manipulation can be carried out under spinal anesthesia and can be done on an ordinary Hawley table with minimal assistance.

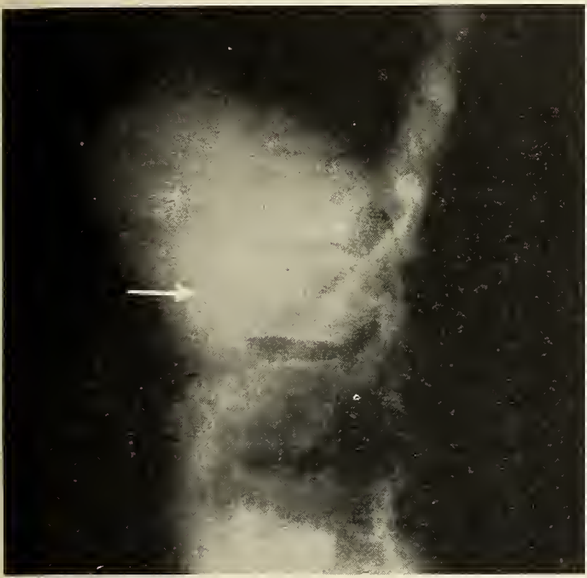

Fig. 9. Case 2 after reduction.

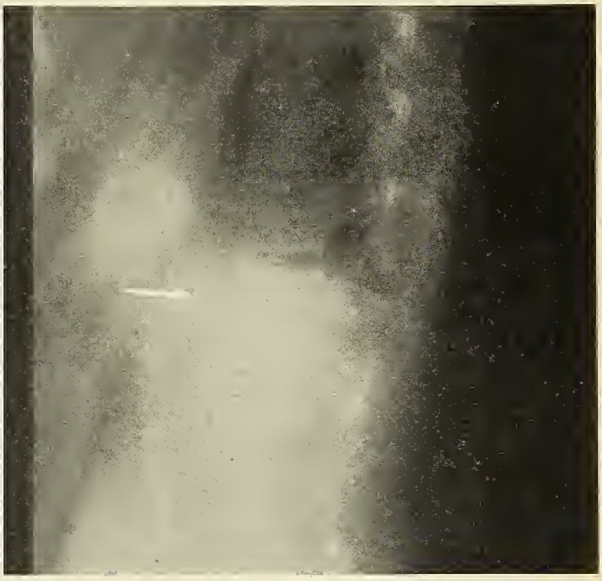

Fig. 10. Case 2. X-ray five months after reduction.

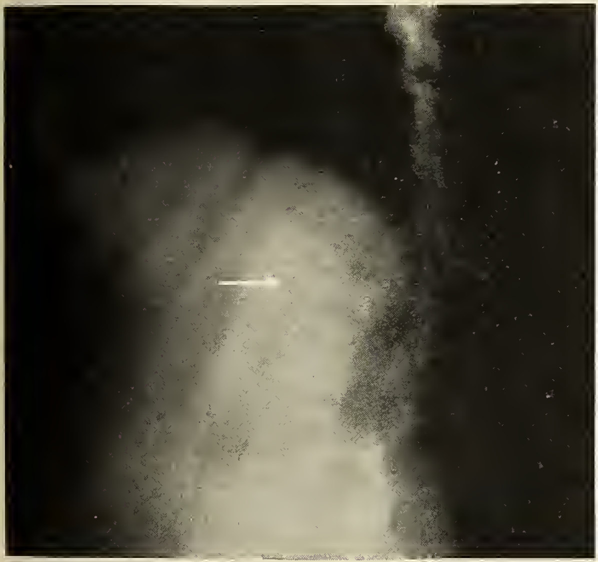

Fig. 11. Case 3. X-ray before reduction showing compression of first lumbar vertebra.

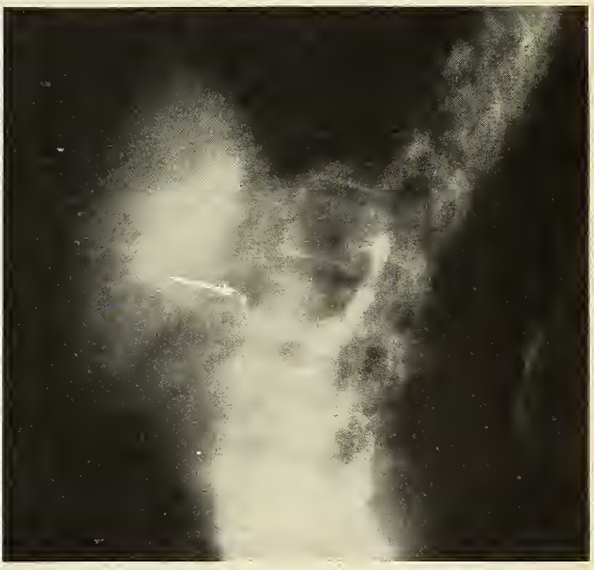

Fig. 12. Case 3 after reduction. Note correction of kyphosis as seen in Figure 11.

METHOD

The patient is given a preliminary hypodermic of sodium luminal, and then 100 to 150 milligrams of novocain dissolved in spinal fluid are injected intraspinally, and the patient placed upon an ordinary Hawley table (Fig. 1). The spinal anesthetic gives perfect relaxation and eliminates all pain. The feet are then fastened to the foot supports to obtain countertraction. The spine is protected by heavy pads of felt, then a heavy muslin bandage is fastened around the body directly over the injured vertebra, and the operator and his assistant lift this portion of the spine, thus creating hyperextension, and fasten the muslin to the horizontal bars directly above the patient (Figs. 2 and 3). With the patient in this position the operator then can create more extension and more gentle manipulation by locking his arms under the spine and under the arms of the patient. Gentle rocking of the spine from side to side and putting direct pressure over the injured vertebra aid materially. These can be done with absolutely no pain to the patient, and can be done very leisurely and with minimal effort. A plaster cast is then applied with the patient in the hyperextended position, care being taken to have the cast high on the chest and low on the pelvis, so that there may be three fixed points of leverage: high on the chest, low on the pelvis anteriorly, and directly over the injured vertebra posteriorly (Fig. 4). After the plaster cast is sufficiently dry and hard a large window may be cut over the upper abdomen to facilitate breathing. The patient is transferred from the Hawley table to bed, where he remains for approximately two months. During this time he may turn freely upon his side or upon his abdomen, but is not allowed to sit or stand. He is not even allowed into the semi-recumbent position until the two months are nearly up. Following the two months' period in bed a well fitting steel brace is made which keeps the spine in hyperextension and he is then gradually allowed onto his feet. The brace is worn for approximately six to nine months, during the latter portion of which period he is allowed to do practically all of his normal labor.

A precaution to be exercised should be noted: very careful scrutiny of the X-ray to discover or rule out a fracture of the lamina or lateral mass. If this were present and unrecognized serious damage to the cord might result. With great care, however, maintaining very strong traction, even a fracture dislocation can be corrected, as witness Davis' Case 7. Even more care must be exercised in those cases already exhibiting cord involvement, and only the thoroughly trained should attempt manipulation of these.

SUMMARY

1. A plea is made for earlier diagnosis of fractures of the vertebræ.
2. It is pointed out that compression fractures of the spine may be corrected so that the body of the vertebra can be returned almost to normal shape.
3. Holding the vertebra in this new position allows regeneration of bone so that there is no permanent disability.
4. The method consists of hyperextension.
5. Spinal anesthesia offers an excellent anesthetic.
6. The manipulation on the Hawley table offers an easy method of carrying out the manipulation.
7. Care should be taken to look carefully for fracture of lamina or lateral mass to avoid injury to the cord.

CASE REPORTS

Case 1.—H. U. M., 45 years of age, married, a banker by occupation, was in an auto accident March 23, 1930, in which his car went into a ditch. He felt a sharp pain in the back and was brought to St. Luke's hospital about 8 p. m. complaining of pain in the lower thoracic region.

Examination revealed no paralysis of the legs or arms and no disturbance of sensation. X-ray revealed a compression of the 11th thoracic vertebra (Fig. 5). He was placed on a fracture bed and given 10 gr. of veronal.

The next morning after a preliminary hypo of morphine (gr. ¼), a spinal anesthesia (using 150 mg. of novocain) was given, and the patient placed on a Hawley table. Hyperextension was accomplished by the method described above and a plaster-of-Paris cast applied (Fig. 6).

The patient remained in bed in the hospital three or four days and was then transferred by ambulance to his home. Considerable abdominal distress from distention lasted for about seven or eight days. He remained in bed at home for two months and then was allowed to get up gradually after a well fitting brace had been applied. The brace was worn seven months. X-ray examination in December showed bony replacement of the crushed trabeculæ (Fig. 7). No pain was experienced on motion. The patient was able to do his former work.

Case 2.—A. O., aged 31, married, a female, was injured in an auto accident June 20, 1930.

X-ray showed compression of the 12th thoracic vertebra (Fig. 8). No paralysis nor sensory disturbance resulted. The fracture was reduced June 21, 1930, under spinal anesthesia (150 mg. novocain). X-ray showed a good reduction (Fig. 9). Considerable abdominal discomfort lasted for five days. The patient remained in the hospital nearly three months. After two months the cast was replaced by a brace. X-ray in November showed good healing (Fig. 10).

Case 3.—T. J. H., aged 45, married, female, was pushed into a sitting position by an auto backing into her. She experienced a sharp pain in the back.

X-ray showed a compression of the first lumbar vertebra. No nerve injury was found (Fig. 11).

The patient was first seen on November 24, when the fracture was reduced and a cast applied under spinal anesthesia. There was moderate abdominal discomfort four days. Subsequent X-ray showed good correction (Fig. 12).

RACIAL DIFFERENCES IN BLOOD PRESSURE*

HAROLD S. DIEHL, M.A., M.D.
Minneapolis

REPORTS over a period of several years have suggested differences in the blood pressure levels of certain races. Musgrave and Sisson[1] in 1910 found the mean systolic blood pressure of thirty adult male Filipinos to be 108 mm. of mercury. Chamberlain[2] in the following year examined 156 Filipinos between 15 and 25 years of age and found that they had an average systolic pressure of 114.7 mm. From this he concluded that the blood pressures of the Filipinos are practically identical with pressures of the whites. On the other hand, Concepcion and Bulatao[3] in 1916 studied the blood pressures of 362 male Filipino students and convicts between the ages of 15 and 30 years, and reported for the group, as a whole, a mean systolic pressure of 111.5 mm. and a mean diastolic pressure of 76.9 mm.

The Chinese also have been said by practically every writer to have blood pressures distinctly lower than the usually accepted standards for members of the white race. Tung[4] summarized some of the more representative reports of blood pressure studies on the Chinese in the table here reproduced.

TABLE I
BLOOD PRESSURES OF THE CHINESE

Author	*Part of China*	*Number of Subjects*	*Ages*	*Mean Blood Pressure*	
				Systolic	*Diastolic*
Kao (Nat. M.J. China) 8:101, 1922	Central China	63	21-25	116 mm.	71 mm.
Cadbury (China M.J.) 37:823, 1923	South China	700	15-30	101 mm.	65 mm.
Kilbourn (China M.J.) 40:1, 1926	West China	741	14-31	111 mm.	70 mm.
Ying (China M.J.) 40:641, 1926	East China	182	21-50	113 mm.	72 mm.

The mean systolic and diastolic pressures of the 1686 Chinese subjects included in these studies are 107.3 mm. and 68.2 mm. respectively.

Donisson[5] states that the blood pressures of the natives of Africa are practically the same as the pressures of whites in the temperate zone. His basis for this statement is the fact that in a group of 200 natives between 20 and 30 years of age in the interior of Africa he obtained a mean systolic pressure of 124.67 mm., and a mean diastolic pressure of 82 mm. His figures for older age groups were much lower, 200 cases between 50 and 60 years of age showing a mean systolic pressure of 108.1 mm. and a mean diastolic pressure of 71.8 mm. These lower mean pressures of the older group raise the question as to whether excitement may not have been an important factor in raising the pressures of the younger groups.

PRESENT STUDY

In order to further investigate the racial differences in blood pressure, the pressure of American born and foreign born male students attending the University of Minnesota have been analyzed. For the purposes of this analysis only students between 19 and 29 years of age have been included. All blood pressure readings were taken in the same manner and under similar conditions, but undetermined differences exist in the length of time which these students had been away from their native lands. For purposes of comparison, the pressures of a group of Chippewa Indians† of the same age and sex are included.

RESULTS

In Table II both median and mean pressures are shown, with the median listed first as the pressure most characteristic of the group. Age, height, weight, and percentage of standard weight, according to age and height, are included in the table because of the relationship which these factors frequently bear to the blood pressure.

---

*From the Students' Health Service, University of Minnesota.

†The blood pressures of the Indians were supplied by the Minnesota State Board of Health.

The median systolic pressures of students from the Philippine Islands, China, and Japan are the lowest of the groups studied. The pressures of the American Negroes are approximately the same as the pressures of the yellow races, the median being slightly higher but the mean slightly lower than for the Chinese, Japanese and Filipinos. Within the white race, several groups have been set up. Of these, the Eastern European Jews show a median pressure of 120 mm.; native born Americans, 120 mm.; and the Scandinavians, 122 mm. Highest of all were the American Indians with a median pressure of 128 mm. and a mean of 124.9 mm. To the Indians, of course, physical examinations were less of a routine procedure than to the University students; hence, it is very possible that greater excitement may have contributed materially to the high pressures exhibited by them.

The relations between the diastolic pressures of the several groups were similar to the relations between their systolic pressures, except for the Filipinos, whose systolic pressures were low but diastolic pressures relatively high. No explanation for this is apparent but the observation is in accord with the findings of others.[6]

The ages of the groups included in the study were sufficiently uniform to render age an unimportant factor as a cause for the differences in blood pressure. The differences in weight, and in the weight-height-age relationship of the several groups correspond in some instances to the differences in blood pressure; in others, however, this parallelism does not hold true. For example, the negroes have next to the lowest blood pressure with the highest weight-height-age percentage. This would make it appear likely that some factor other than size is responsible for the differences observed in the blood pressure.

COMMENT

These findings naturally raise the question as to whether there are true racial differences in blood pressure, or whether the differences observed are due to such conditions as climate, diet, habits of life, etc. Musgrave and Sisson[1] report that American soldiers in the Philippine Islands show a decrease of about 10 per cent. in systolic blood pressure over a period of several years. Foster[7] and Tung[4] report a similar drop in the blood pressure of Americans who have taken up their residence in China. On the other hand,

Table II

BLOOD PRESSURE OF STUDENTS FROM VARIOUS COUNTRIES

Native Country	Number of Cases	Mean Age in Years	Systolic Pressure Median mm.	Systolic Pressure Mean mm.	Diastolic Pressure Median mm.	Diastolic Pressure Mean mm.	Mean Height in Inches	Mean Weight in Pounds	% of Standard Weight
Philippine Islands	36	22.3±.4	112	116.5±1.5	78	77.4±1.2	63.7±0.3	114.7±1.3	90.8±0.7
China, Japan, Korea	28	22.3±.3	114	113.9±1.3	70	71.4±1.1	66.0±0.3	121.3±1.4	87.0±0.9
American Negroes	25	20.0±.4	115	114.0±1.2	72	73.2±1.0	66.9±0.3	137.0±2.8	102.4±1.8
Eastern European Jews	41	19.6±.3	120	119.4±1.1	73	72.7±0.9	65.8±0.3	131.7±1.5	100.1±1.0
American Students (White) (both parents born in U. S.)	542	20.3±.2	120	122.0±0.4	75	76.0±0.3	68.7±0.2	142.4±0.5	101.6±0.3
Scandinavian Countries	30	22.8±.4	122	122.5±1.2	78	76.8±0.8	68.7±0.4	147.3±1.7	97.8±1.0
American Indians	34	19.8±.7	128	124.9±1.2	80	76.6±1.1			

The standards used for weight according to age and height were those developed by the Medico-Actuarial Society of America.

Harris, quoted by Foster,[7] manager of the North China Division of the Sun Life Insurance Company, Shanghai, states that "in our experience the blood pressure of the Chinese is considerably lower than the blood pressure of the Caucasian races. The blood pressure of the white races, that is, the Europeans and Americans in China, is, however, in our experience, just the same as the blood pressure in such races in Europe and America. We are also of the opinion that hypertension in foreigners is just as common in China as in western countries and that hypertension is rare in the Chinese." Roddis and Cooper[8] found that the blood pressures of 173 American naval officers in the tropics were about 11.5 mm. below the level considered normal in the temperate zone; and Mukherjee[9] states that the basal metabolic rate of Europeans in the tropics is below European standards.

These decreases of metabolism and blood pressure in the tropics are believed by Roddis and Cooper to be due primarily to alterations in physical activities. Alvarez's[10] observation that the most typical systolic blood pressure of prisoners in a state penitentiary was 115 mm. of mercury and that the pressure did not exhibit the expected increase with age tends to support this theory. On the other hand, the observations here presented strongly suggests that when individuals of different races are living under the same or similar conditions there still exists a basic difference in the blood pressure level. It is entirely possible, of course, that the lower blood pressures of certain races may be the result of long continued differences in habits, customs, and modes of living.

SUMMARY

1. Differences exist in the mean and median blood pressure of certain racial groups of students at the University of Minnesota.

2. The Filipinos, Chinese, and Japanese exhibit the lowest median systolic pressures; the pressures of negroes were slightly, though not significantly, higher; while the Americans and the Scandinavians had the highest pressures of any of the student groups.

3. The relation of the diastolic pressures of the various groups is similar to the relation of the systolic pressures, except that the Filipinos with a low systolic pressure have a relatively high diastolic pressure.

4. A group of Chippewa Indians of the same age and sex as the University students, but examined under somewhat different conditions, had higher systolic pressures than any of the student groups.

SOME OF THE PRESENT METHODS USED IN THE DIAGNOSIS AND TREATMENT OF PROSTATIC HYPERTROPHY*

Gilbert J. Thomas, M.D., F.A.C.S., and E. W. Exley, M.D.
Minneapolis

MOST urologists and many surgeons recognize the necessity of preoperative treatment of the patient who requires prostatectomy, and are aware of the lower mortality since this treatment has been used. In a paper,[2] read before this society in 1927, we stressed the importance of careful preoperative treatment, and emphasized some phases of this technic.

We have never been satisfied with the mortality occurring during the preoperative stage of prostatectomy. When we add this to the present operative mortality, we find the total is not as low as it should be. We have apparently transferred much of our operative mortality of twenty years ago to a present-day preoperative mortality. Is there anything more that we, as urologists, may do to lower the morbidity and mortality of the patient with hypertrophy of the prostate, whether preoperative or operative?

Our discussion here will dwell upon our experience with additional phases of preoperative and operative technic that in our opinion have a direct relationship to morbidity and mortality.

The Necessity of a Careful Physical Survey Before Preoperative Treatment is Begun.—We have found a careful physical survey of the patient of great importance before any preoperative treatment is started. This has become a rule because from experience we know that in many instances our preoperative treatment would either not have been started, or would have been changed, had we known the findings of a complete physical examination. Excepting in emergencies, a patient with hypertrophy of the prostate should not have more of a urologic examination than the finger palpation of the rectum, urinalysis and X-ray before the results of a complete physical survey, together with blood chemistry and electrocardiogram, are known. Our internists know the difficulties that the sufferer with prostatic disease may have during his preoperative and operative treatment, and of the importance of discovering lesions before preoperative treatment is begun. Having this coöperation, we do not begin preoperative treatment until the physician assures us that the patient has no condition that may give rise to complications or contribute to morbidity or mortality. The internists are thorough in their search for foci of infection. They have taught us that a patient with any cardio-vascular lesion should have more careful and possibly more prolonged preoperative treatment than a patient with normal findings.

One of our internists warned us some six months ago concerning one of our patients who had some râles in the base of one chest cavity. We were told that this man might develop pneumonia following the slightest exposure to infection, and suprapubic drainage was suggested for a few months, during which time the lung condition might be treated. This advice was accepted, and three weeks ago we were able to remove this man's prostate, which was followed by an uneventful recovery.

The Role of Infection in the Preoperative and Operative Phases of Prostatic Surgery.—Infection in the epididymis still remains a troublesome complication during the preoperative and postoperative stages of prostate disease. A double vasotomy done before catheters or other instruments are passed through the urethra reduces this painful and distressing complication to a minimum. In a paper read at the last session of the American Urological Association,[3] we emphasized the role of infection in the production of mortality in patients suffering from prostatic hypertrophy with the following summary:

I. Any type of catheter drainage of the bladder may introduce infection into the urinary tract, and, by traumatizing the urethra, introduce infection into the blood stream, both of which conditions become a factor in producing mortality.

II. In 93 per cent of the autopsy records studied, old or recent urinary infection was a major factor in the production of death.

III. Cardiovascular disease without urinary infection was a factor in producing death in only 7 per cent of the cases.

---

*From the Department of Urology and Dermatology, The Nicollet Clinic, Minneapolis, Minnesota. Read before the seventh annual meeting of the North Central Branch of the American Urological Association, Indianapolis, Indiana, October 23–25, 1930.

IV. Bronchopneumonia was the cause of death in 46 per cent of the cases reported. In only two cases in this group did the autopsy findings fail to reveal evidence of a severe genitourinary infection.

V. Forty per cent of the total number of deaths occurred during the preoperative treatment.

VI. The average number of days of preoperative urethral catheter drainage was nineteen. No conclusion could be drawn from our study of the duration of a catheter drainage.

From experience we know that infection may reach the blood stream when a catheter or other instruments pass through the urethra. This additional hematogenous infection when carried to partially damaged kidneys has been sufficient to interfere with their function so that a fatal uremia has developed. For this reason we recognize the importance of the more careful handling of the over-distended bladder. In the treatment of this condition we believe that the methods used by many of us are not satisfactory. Many urologists are in the habit of using the indwelling permanent urethral catheter with gradual decompression to relieve chronically over-distended bladders. It seems to us that with this and other methods now being used little attention has been given to the proper control of infection.

Our study of postmortem material indicates that urinary infection is a primary cause of death much more often than embarrassment of kidney function, which follows as the result of pressure from an overdistended bladder, ureters and kidney pelves. However, both of these factors may operate to produce morbidity and mortality. Infection introduced into the blood stream is frequently carried to the kidneys. Here the infection finds the defense mechanism low because of interference from residual urine in the bladder, ureters and kidney pelves, so that inflammation with the production of chills and fever begins.

If preoperative treatment consisted in merely removing the residual urine so that back pressure on the upper urinary might be relieved, our problem would be solved and our preoperative mortality would be nil.

Over-distention lowers the resistance of the urinary tract, but we doubt that this condition alone may exist long enough to completely destroy the kidneys without infection. However, infection is more liable to occur with over-distion than without it.

We have been able to reduce our morbidity, and probably our mortality rate, by not attempting gradual decompression of the chronically over-distended bladder with the introduction of catheters through the urethra.

When we find a patient who has prostatic symptoms and palpable enlargement of the prostate, together with normal blood chemistry findings and slight residual urine with only a moderate infection in otherwise normal urine, we believe that repeated catheterization, and eventually a permanent catheter, may be used. In other words, we find some patients whose general condition is such that we believe their kidneys can withstand the amount of infection which may be introduced by the use of urethral catheters, either temporarily introduced, or for permanent drainage. We find it difficult, however, to judge the border line case that may withstand catheterization or may require suprapubic drainage. When in doubt, careful suprapubic drainage without contamination of the prevesical space should be done.

Examination of Urological Tract.—The urologist should make as complete a study of the urological tract as conditions permit. One cannot always be sure that the prostate is enlarged enough to produce symptoms by palpation per rectum alone. It may contain median and bilateral lobes which project into the bladder and are not palpable per rectum. In some instances it becomes necessary to differentiate between a prostate that is temporarily enlarged because of non-specific prostatitis, and an adenoma, or both. Occasionally we have found it necessary to use the cystoscope before this differentiation could be made. This instrument should not be used, however, until infection has been controlled, and not until drainage of the kidneys and bladder has been completed.

The cystogram will frequently give useful information concerning the size of the prostate and the bladder, and the presence or absence of diverticuli.

We find that many urologists do not watch the pus content of the urine carefully enough. Some method of calculating the number of pus cells per high power field should be used, so that we may know whether infection is increasing or decreasing. The constant occurrence of many pus cells in the urine after adequate drainage of the bladder has been established should direct suspicion toward the upper urinary tract. In a few instances we discovered pyonephrosis and pyoureter which required attention before prostatectomy could be undertaken. It is our opinion that the cystoscope, ureteral catheter and X-ray should be used with the prostatic patient just as they would be used in the diagnosis of any other urological lesion. Before the routine use of X-ray in examinations, large bilateral renal stones have been found which were present before and after prostatectomy.

When cystoscopy is contraindicated or impossible, the use of intravenous urography may give helpful information concerning the upper urinary tract.

To sum up, then, we believe that the preoperative treatment of patients suffering with hypertrophy of the prostate should aim at control of infection and the discovery of lesions in the urinary tract or in other organs which from an internist's point of view might be a factor in increasing morbidity or mortality. From our experience we believe that care in the evaluation of these two factors will materially reduce morbidity and mortality, particularly in the large group of patients who die before prostatectomy is undertaken.

Surgery of the Prostate.—After preoperative treatment has restored the patient's functions to normal, prostatectomy may be undertaken. Careful operative technic will eliminate hemorrhage as a postoperative complication. When the one-step so-called open operation (primary suprapubic prostatectomy) can be done, the control of hemorrhage is not difficult. In order that bleeding may not interfere with our careful enucleation of the prostate, we have been in the habit for the last fifteen years of injecting the prostate and prostatic capsule through a long needle with novocain or salt solution. This method has recently been described by Ballenger,[1] and we like to follow his technic. This controls bleeding so that we are able to see what we are doing at all times, and we have little difficulty in picking up bleeders and tying them when the enucleation is completed.

Careful trimming of the ragged bladder edge and subsequent sewing with interrupted stitches have been great factors in the control of postoperative hemorrhage. In addition to these safeguards, we are in the habit of using a rubber bag partially filled with water in the prostate bed. With this technic we have not had a postoperative hemorrhage during the last four years. We like to sew the bladder to the abdominal wall and attempt to repair the incision of the bladder, so that we have a water-tight opening around the drainage tube. As soon as the patient returns to bed following prostatectomy, antiseptic solutions are introduced into the bladder, which continue our fight against infection. This is continued even after the suprapubic wound is healed. Following the removal of the bag, we do not introduce a catheter through the urethra at once, because we still fear the possibility of carrying infection into the recently operated field. The suprapubic drainage tube is replaced every two or three days with a smaller one, and after the tenth or twelfth day a small catheter may be introduced through the urethra and all suprapubic drainage removed.

Nursing.—The proper care of patients with hypertrophy of the prostate requires the services of a male nurse who has been thoroughly trained and who has nothing else to do. We are sure this type of expert care reduces the patient's stay in the hospital at least a week, and reduces the time that he drains suprapubically from seven to ten days.

Anesthesia.—After trying several general anesthetics, we have come to rely on spinal as the anesthesia of choice for prostatectomy or cystotomy. Our second choice is hyoscin and morphine, plus infiltration both of the suprapubic area and of the prostate.

SUMMARY

1. Preoperative examination of patients suffering with hypertrophy of the prostate is of tremendous importance, and therefore must be very thorough, and every finding properly evaluated before the plan of preoperative and operative treatment is determined.

2. In the preoperative treatment of the prostatic patient the urologist's aim should be to control and relieve infection in the urinary tract.

3. Infection present in the urinary tract, together with that introduced by instrumentation, causes a bacteremia which is responsible for the majority of deaths occurring during the treatment of these patients.

4. The fight against urinary infection should be continued during postoperative convalescence and until the patient is returned to normal health.

5. The type of anesthetic to be used should be chosen to fit the patient. Our experience teaches us that spinal or hyoscin and morphine hypnosis, plus infiltration, are the best methods.

6. The technic of surgical removal of the prostate should be directed to the control of hemorrhage. We believe that this may be best accomplished by a technic that permits the surgeon to view the field.

7. The services of a specially trained male nurse are invaluable in the care of the prostate patient.

CASE REPORTS

TRAUMATIC APPENDICITIS*

REPORT OF CASE

Willard D. White, M.D.
Minneapolis

Not long ago I was present at an autopsy which was performed on the body of a young man who received an injury to his abdomen and who had subsequently developed appendicitis, peritonitis and died. The history was that this man had apparently been well until September 30, 1929, when, while cranking an auto truck, the engine back fired and the handle of the crank struck him in the abdomen so that he complained of pain to a fellow workman who was with him at the time. They eventually got the motor started, and he drove the truck a number of blocks and left it at his destination. He went home and complained to his wife that he had pain in the abdomen. He sat down to dinner, ate very little and, although there was company at his house for dinner, he went to bed very soon after the meal, stating that he did not feel well. He vomited early in the evening and slept very little during the night. The next day his pain became more severe but gradually subsided. A physician was called who obtained the history as just outlined, examined the patient and stated that in his opinion the man was very likely suffering from appendicitis but that he probably was over the worst part of the attack and that he probably would recover without operation.

On October 4, four days after the blow on the abdomen, the same physician was again called and found that the symptoms were much worse. He had the man sent to the hospital and operated on him the same evening, and found a gangrenous appendix incompletely walled off and a small amount of pus. The appendix was removed and drains were inserted. On entrance to the hospital his temperature was 100.8, pulse 108. From the fourth postoperative day on there was an increase in the temperature and pulse rate, he was irrational at times and he died on October 13, 1929, fourteen days after the accident and nine days after his operation. He was buried. Later the question arose of the relationship of the blow on the abdomen to the development of his appendicitis and death, and an autopsy was performed on November 23, 1929, about six weeks after his death. Definite evidence of peritonitis was found. There was no dispute about the fact that he had appendicitis and peritonitis. Apparently there was no question about the fact that he received a blow on the abdomen which caused him to complain, nor that he was feeling well up to the time he received the blow and that symptoms began soon after.

I have asked a number of men of considerable medical and surgical experience their opinions about traumatic appendicitis and whether they had seen such cases. The usual reply has been that the appendix was such a mobile and well protected viscus that it is very rarely traumatized unless some extreme force or crushing blow does such extensive damage to the abdominal wall and trunk that the appendix is included with other tissues damaged by the force. On looking up the literature I found that traumatic appendicitis is by no means such a rare condition and many cases are cited where an apparently healthy individual receives a blow on the abdomen and promptly develops appendicitis.

It is true that the appendix is a deeply situated and mobile organ and that this location and mobility are protecting factors against direct trauma. It appears, however, that traumatic appendicitis results from a blow on the abdomen which involves certain other factors.

The lumen of the appendix is continuous with that of the cecum and the contents of the bowel enter the appendix freely, remain there for a time and then are expelled into the cecum. The cecal and appendiceal contents are at all times laden with bacteria capable of invading the appendiceal wall under favorable conditions. We know from observing patients who have been given a barium meal or enema under the fluoroscope that with relatively slight pressure material can be forced from the cecum into the appendix. It may remain for a few moments, hours or for several days.

Experimenters (Furbinger and Von Hansemann) were able to express the contents of a full cecum into the appendix by light manual pressure over the cecum, by light manual pressure over the ascending colon and by introduction of air into the rectum. They used colored fluids as an indicator.

Let us now consider what may happen if a blow is received on the abdomen sufficient to cause a violent contraction of the muscles and increase the intra-abdominal pressure. Several things may happen as far as the appendix is concerned.

1. The bowel content may be forced into the appendix sufficiently to produce a moderate distention of the appendix but the elasticity of the appendiceal wall forces the bowel material back into the cecum, when the pressure decreases and no untoward effect is noted.

2. The force may be sufficient to distend the appendix beyond its physiological limit, producing minute cracks or tears in the lining of the appendix and these allow the bacteria which are always present in the lumen to invade the wall of the appendix and produce disease.

3. The force may be sufficiently strong to produce

---

*Read before the Minneapolis Surgical Society at its meeting of March 5, 1931.

not only cracks in the mucous membrane or muscle coats but it may actually cause a rupture through the wall of the appendix allowing immediate spilling of the bowel content into the peritoneal cavity.

4. Let us now consider what may happen in an appendix in which a fecalith is present which is too large to be expelled through the ileocecal valve. The bowel content is forced into the appendix and the muscle of the appendiceal wall attempts to force the fecal material back into the cecum but the opening becomes obstructed by the fecalith. If the material is now confined within the appendix under pressure, a stasis results. These conditions favor the growth of bacteria. Pressure is developed further, the resistance of the mucous membrane is damaged more and invasion of the wall is greatly favored. If the appendix has been the seat of previous attacks of inflammation which have caused kinking of the appendix and the formation of adhesions, these factors will make it even more difficult for the appendix to be emptied. As the pressure in the lumen of the appendix increases, distension follows. The circulation in the wall of the appendix is progressively impaired. Perforation is very apt to occur.

Another factor of importance is that a fecalith or coprolith is evidence of a pre-existing inflammation in the appendix. It is formed in that stage of the inflammation when the secretions are increased and it is made up of fecal material mixed with bacteria and inspissated mucus. Later this material becomes drier and hardens by chemical change and absorption. The mucosal crypts may be flattened out by contact with it. Aschoff[8] states that the primary or most active focus of infection is just distal to the coprolith.

As Ludington gives them: The conditions favorable for the development of a traumatic appendicitis are: (a) having the lumen obstructed by a coprolith; (b) fecal stasis in and defective drainage of the distal segment; and (c) an increase in the virulence of the contained organisms due to their confinement. When these conditions are present, if an excess of fecal contents is forced into the appendix it must either push the coprolith farther into the appendix or flow over and around the obstruction, filling and distending the terminal segment. Quoting from Ludington: "The immediate result of the afflux of cecal contents is pain from the distension of the appendix and from its efforts to empty itself. The distended appendiceal wall is rendered anemic by pressure, particularly in its mucosal layer. The virulence of the organisms is heightened by the establishment through the fecal stasis of conditions favorable to their development. These factors eventuate in an immediate and destructive invasion of the appendix wall."

The danger of active purgatives in appendicitis is recognized and Berkley Moynihan's alliterative sequence of pain, aperient, perforation represents the same mechanism as that obtained in a traumatic case, but substitutes as the propelling force the hypermobility of the stimulated intestine in the place of direct external pressure.

It will be seen, therefore, that the mere fact that a blow applied to the abdomen does not cause traumatic appendicitis by actual bruising of the appendix itself but causes it by overdistention of the appendix by increasing the pressure within the cecum, forcing the material into the appendix. It is apparent and readily admitted that this forcing of the cecal content into the appendix occurs a great many times and no appendiceal disease follows, but when conditions are right a blow on the abdomen can and does instigate an attack of appendicitis. The fact that trauma can and does play an important rôle in the production of appendicitis should be appreciated by medical men. Indeed careful reading of the literature shows that it is appreciated and recognized.

Howard A. Kelly wrote a book on "The Vermiform Appendix," published in 1905, and devotes considerable space to traumatic appendicitis and gives an outline of the history of fifty cases. These cases included individuals from two to forty-nine years of age. As one would expect, males were much more frequently affected than females, forty-one being males, and eight females. The sex was not mentioned in one case. It is interesting to note that in his fifty cases there was no evidence of external violence to the abdomen such as contusion or laceration in any instance. There was evidence of previous morbid condition in the appendix in thirty of his fifty cases.

Osler[7] states that persons whose work necessitates the lifting of heavy weights seem more prone to the disease and that trauma plays a very definite rôle and that in a number of cases symptoms have followed very closely a fall or a blow.

John B. Murphy[3] states that as early as 1892 he had called attention to the fact that trauma was occasionally an exciting factor in appendicitis and recognized that if the lumen is obstructed by fecal concretions the circulation of the wall of the appendix could be interfered with.

Ludington's[5] three cases were interesting. One was in a ten-year-old girl who fell from a swing, a distance of about two feet, and landed prone on level ground. Pain was immediate and severe. Vomiting followed and eighteen hours after the fall all the symptoms of peritonitis were obvious and operation thirty-six hours after the fall disclosed an appendix acutely angulated at its mid-point by a single firm adhesion. Immediately distal to the point of angulation an actively advancing peritonitis was present. His second case was that of a boy, nine years of age, who was enjoying the first sliding of the winter by "belly flopping" on a sled. He abandoned his sport on account of abdominal pain. Vomiting followed, and seventy-two hours afterwards a gangrenous appendix, containing a coprolith, was removed. His third case was that of a girl, nineteen, who thought she might have had appendicitis on account of pain in the right lower quadrant which recurred at intervals. She was examined carefully, her abdominal wall was thin, and deep palpation in the right lower quadrant failed to reveal evidence leading to a diagnosis of appendicitis. She was advised to go home and take a laxative, which she did, but on leaving the office she stated that the examination caused aching in the right lower quadrant. The ache grew worse and at 5 a. m., sixteen hours after the examination, the appendix perforated and at operation, later, a perforated appendix which contained a coprolith was found.

Addison H. Bissell[2] reports four cases. The first case was in a fourteen-year-old boy who had not had a previous attack of appendicitis. While playing football he fell forward striking his abdomen on a rock. He felt severe abdominal pain immediately and vomited. The abdominal pain was severe at first but lessened somewhat after an hour. It was, however, constantly present up to the time of the operation the day following the accident, at which time the wall of the cecum was injected and thickened. The right iliac fossa was the site of a large abscess and free in this abscess was a fecalith. The appendix was long, its distal half was necrotic and near the tip was a perforation, one inch long, opposite the attachment of the mesentery. The second case was in a ten-year-old boy without any previous history of appendicitis, who received a severe kick in the abdomen while playing football. He felt immediate abdominal pain, was nauseated and vomited. He felt pain in the upright position and was chilly. He was kept in bed at home for six days without being seen by a physician and he suffered constantly from severe abdominal pain and nausea, vomiting, chills, distension and constipation. On the sixth day he was sent to the hospital by a physician and operated upon immediately, and marked generalized fibrinopurulent peritonitis was present. Near the tip of the appendix was a perforation, one inch long, with markedly thickened everted edges. A large concretion was found in the part near the perforation, which was on the external lateral aspect of the appendix. Case 3 was that of a nineteen-year-old boy who had not had any previous attack of appendicitis. Forty hours before operation he had been thrown on his back while wrestling and his opponent had jumped on his abdomen. He felt immediate colicky abdominal pain, he was nauseated and vomited. At the operation the appendix was found to be four inches long, in normal position and not adherent. The entire appendix was markedly inflamed. The distal half was necrotic. There was a perforation, one inch long, near the tip of the anti-mesenteric side. A general peritonitis was present without the slightest evidence of any walling off. He did not show any improvement after his operation and died on the third day. Two concretions were found in the region of the appendix. Free purulent material filled the abdominal cavity.

Case 4. A boy, aged 18, who had not had any previous attacks of appendicitis, fell hard while skating, striking his buttocks. He felt pain immediately around the navel and in the right lower quadrant. He felt faint and chilly, was nauseated, and vomited. He was first seen by Dr. Bissell twenty-six hours after his fall and an appendectomy was immediately performed. A general peritonitis was present. A large abscessed cavity was observed in the right lower quadrant and a concretion was found in this cavity. The appendix was 2.5 inches long, its wall thickened and necrotic. Near the tip a perforation, one inch long, with everted edges was found.

Dr. Richard J. Behan[1] of Pittsburgh reported a case in a young man, twenty-eight years old, who fell over a tomato patch, landing on a sewer crock, inflicting a bruise on the left side of the abdomen. From this time on he had severe pain in the abdomen which was more or less constant. After the first severe onset the tendency was for the pain to be localized in the right side. Three weeks after this first injury he had a sudden exacerbation of pain in the abdomen with nausea, weakness and general malaise. Operation revealed a large abscess in the region of the appendix with the cecum firmly bound down to the lateral peritoneal wall and over 400 c.c. of dark foul liquid was removed from the peritoneal cavity, by means of the suction apparatus.

No attempt will be made in this article to collect all of the cases of traumatic appendicitis reported in the literature, but many cases are encountered where a blow on the abdomen is followed almost immediately by symptoms which we ordinarily recognize as those of appendicitis and subsequent operation has revealed a gangrenous appendix, and in a great many of these cases fecal concretions are obtained.

The relationship of trauma to the abdomen with a subsequent development of appendicitis is of importance not only in a general medical way but also from a medico-legal standpoint as well. Of course, it is a well known fact people are very prone establish a connection between any disability and an accident which may furnish a possible cause for it and this is especially true if the question of compensation or liability enters into it. It is a common thing to see patients who will ascribe the production of a tumor of the breast or abdomen to a bruise or fall and if the patient has pain in his extremities which might be due to a rheumatism or neuritis it is not unusual to have such a patient give as his opinion that the symptoms were present because some accident had happened to him at some time or other. This factor is well recognized. Nevertheless, we must also admit that there is such a clinical entity as traumatic appendicitis "and that such testimony to that effect must be given, when the facts warrant it, with assurance, whether it be for or against an individual or association."[4]

"To argue as to whether the organ was normal or not is beside the point, for the abnormalities that make for easy invasion of the appendix by infection after injury are compatible with good health, and the question should be whether an abdominal injury, or unusual strain, precipitates the clinical picture of acute appendicitis. There does not need to be any doubt that this can take place. The trauma is the deciding factor." (Bissell.[2])

Another important factor to be considered is that when the appendix has been removed and is examined in the laboratory it is impossible to state whether or not this appendix which might be gangrenous and perforated was a traumatic appendicitis. One's opinion in that regard is formed on the careful history which describes the circumstances immediately preceding the events and condition of the patient immediately preceding the trauma and accurate description and understanding of what occurred at the time that the trauma was received, the time relationship between the trauma and the onset and development of symptoms and finally the findings at operation. All of these factors are taken into consideration in forming that opinion as to whether or not the case in question is one of traumatic appendicitis.

I do not claim to bring forth anything new or original in this discussion but my reason for bringing up the subject is to call attention to the fact again that there is such a thing as traumatic appendicitis and it is our duty to recognize it.

CONGENITAL INTESTINAL OBSTRUCTION

REPORT OF CASE

Fred H. Stangl, M.D.
St. Cloud

Symptoms of bowel obstruction, seen within the first few days of life, are, almost without exception, due to congenital maldevelopment of the gastrointestinal tract. It is true that intussusception in the new-born takes place, as shown by the reports of Gelston and Sappington (1) and Steele (2), but this is most unusual. Of the mal-developments, imperforate anus is four itmes as frequent as all other atresias, according to Davis and Poynter (3), and is very easily recognized and surgically cured. Anomalies of the intestines proper are less frequent and Miller (4) gives their occurrence as one in every 15,000 to 20,000 births. Anatomically the duodenum, the ileum, the jejunum, or colon, are the usual locations; of these the frequency is shown by the following tabulation of Davis and Poynter (3):

	Cases
Duodenum, above the papilla	59
Duodenum, below papilla	75
Jejunum	66
Ileum and cecum	101
Colon	39
Multiple atresia	67

Numerous causes have been given for these atresias. Tandler (5) and Forssner (6) maintain that failure of epithelial plugs to canalize is the cause and the former has demonstrated such a plug in the duodenum of fetuses of four to ten weeks. Vascular sclerosis or anomalies are believed by Davis and Poynter (3) to result in atrophy and fibrous replacement of developing intestine. Other theories include fibrosis following volvulus, intussusception, anomalous peritoneal bands, and the healed fetal peritonitis reported by Fielder (7).

Symptoms usually do not appear until the infant begins to take food, but excessive abdominal distension and the passage of pale or lanugo-free meconium may be present to suggest intestinal obstruction. Vomiting soon appears. Varying with the location of the obstruction, this begins a few hours after nursing in high obstruction or is delayed for hours in lower obstruction. Occlusion below the papilla results in bile-stained emesis. Blood also may be present. Vomiting is persistent and inanition rapidly ensues. Constipation and obstipation are important symptoms. Meconium may be found if the obstruction is above the opening of the bile duct, but usually true lanugo-containing meconium is not present. Abdominal distention is usually noticeable from birth. Urine is scant and dark colored. Loss of weight is rapid and by the third day the infant's condition is grave.

This pathologic condition may involve any part of the intestine and atresias are often multiple. Duodenal lesions are usually single, and most of them are below the papilla according to Grulee and Bonar.[8] Obstruction may be due to a membrane only, the blind ends may be joined by a cord, or, more rarely, they may be completely separated. At the place of atresia, the proximal intestine terminates in a greatly distended blind sac, with hypertrophied walls.

The diagnosis of atresia of the intestine is usually easy from the symptoms and the demonstration of a blind gut by barium feeding and X-ray.

The treatment is essentially surgical. The prognosis is practically hopeless and reports of only six cases of successful operation for intestinal atresia were found. The first was in 1911 by Tockens,[9] who performed a lateral anastomosis for atresia of the ileum on an infant eight days old. In 1916, Ernst[19] performed a duodenojejunostomy for atresia of the distal half of the duodenum with survival of the patient. Richter[11] of Chicago mentions an infant having atresia at the duodenojejunal angle which he cured by posterior gastroenterostomy. In 1927, Sweet and Robertson[12] reported a patient treated by them on its ninth day of life for atresia of the first portion of the jejunum by gastrojejunostomy. The relief obtained was only partial. At the end of three weeks at a second operation, anastomosis between the dilated duodenum and jejunum was performed with full recovery. Bolling[13] reports two patients having atresia of the duodenum who were well following gastrojejunostomy.

The case reported herewith concerns a male baby, the fourth child of healthy parents, born spontaneously one month prematurely, after but a few hours' labor. No external deformities were present; breathing, heart action, and crying were normal. The birth weight is reported as 5.75 pounds. Birth occurred at 12:15 o'clock p. m. on April 17, 1931, in the family farm home. About forty-eight hours after birth, the family reported that the infant vomited all its food at infrequent intervals. They were instructed to bring the child to the hospital, where it weighed 5 pounds and 1.25 ounces, or 2,295 grams, upon admission at 6.45 p. m. on April 19, 1931, and measured 19 inches long. The skin was dry, slightly icteric and the child looked very sick. The temperature was normal. Urine was dark colored and scant. The bowels moved twice a day but only a small amount of slightly green mucus was expelled. Food was taken greedily. The abdomen was distended and tympanitic. Vomiting occurred once about every sixteen to eighteen hours during the life of the infant. Feedings of a half ounce of breast milk were given seven or eight times a day.

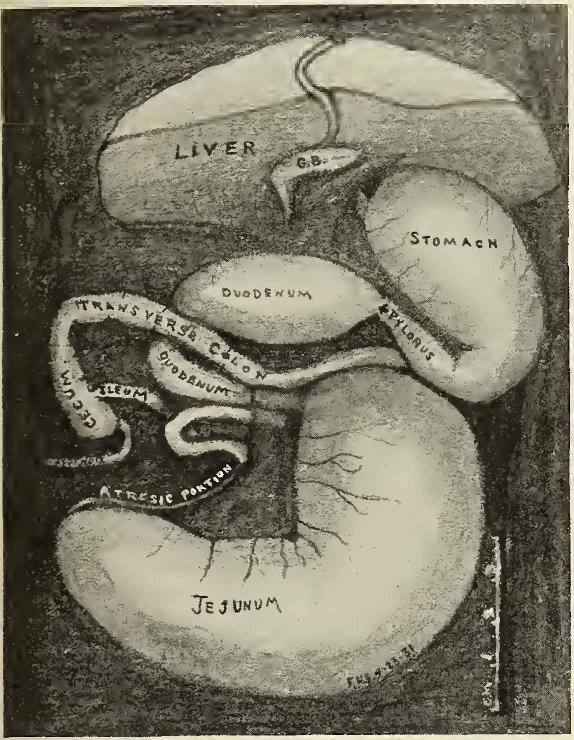

Fig. 1. Illustration is a retouched tracing of the viscera removed at postmortem examination. Atresia due to a 4 cm. fibrous cord of the jejunum with dilation of the intestine and stomach above the obstruction is shown.

X-ray examination revealed a stomach filled with an opaque meal which moved through a dilated duodenum into a very large blind pouch. Diagnosis of congenital obstructive lesion was made by Dr. W. L. Freeman, the roentgenologist.

The infant's condition was poor at all times; therefore surgery was not attempted. The child lived a little over five days, and at death it was deeply jaundiced and weighed 1,910 grams. Essential postmortem findings were a distended stomach and duodenum with a greatly dilated first half of the jejunum, which ended in a blind sac. From this it extended as a solid fibrous cord, 2 to 3 mm. in diameter, for 4 cm.; at this point the patent intestine was again present and continued to be so to the anus. The accompanying illustration is a retouched tracing of the removed organs showing the atresic cord and the general anatomical relations. The mesentery of the atresic cord was practically avascular, giving weight to the opinion that the maldevelopment might be the result of vascular anomaly.

Conclusion.—Congenital atresia of the intestines is relatively infrequent and cases of surgical cure are very few. A case of fibrous atresia of the second portion of the jejunum with postmortem findings and illustrative drawing is reported. Vascular anomaly is a likely cause of the reported case.

TETANUS FOLLOWING INDUCED ABORTION.

REPORT OF CASE WITH RECOVERY

C. H. Mattson, M.D., and T. A. Starkey, M.D.
Saint Paul

TETANUS following induced abortion is a very rare condition. The mortality reported in the literature is very high. Schneider,* in a survey of the literature, found the mortality of 111 cases of puerperal tetanus to be 91 per cent. We, therefore, think it justifiable to report this case.

The patient, a woman, aged 33, white, entered Ancker hospital May 4, 1931, complaining of inability to open her jaw, difficulty in swallowing, and stiffness and pain in her neck. These symptoms, first noticed on May 1, three days before admission, had grown progressively worse until at the time of admission she was unable to take even liquids by mouth, and her upper dental plate could not be removed.

At this time the patient stated that on April 28, 1931, three days before the onset of symptoms, a very small splinter from a broom handle had become lodged in the little finger of her right hand. This broom had never been used outside of her kitchen, and because of the size of the splinter (it measured 3/16 of an inch in length) and the absence of reddening, exudation and any other signs of local reaction, a search was made for another primary focus of infection. None could be found, though a foul smelling, sanguinous vaginal discharge attracted attention. At the time of admission the patient absolutely denied any irregularity in her menstrual cycle. However, a few days later she volunteered the following additional history: Her last normal menstrual period had terminated on January 28, 1931. She admitted having sexual intercourse during the first part of February and had missed her February and March periods. On about April 15th, thinking she was pregnant, she went to a midwife, who introduced a rubber catheter into the uterus. This was removed in twenty-four hours, following which she had a few cramps and within a day or two passed a liver-like mass. There had been no chills or elevation of temperature, though the foul, sanguinous discharge noted on admission had been present since then.

---

*Medizin, Klinik, Jan. 22, 1926.

This abortion was performed approximately two weeks before the onset of her first symptoms.

The patient also stated that during the month of March and the first week in April a pink rash had been present over the skin of her back, chest and abdomen. It disappeared spontaneously.

There was nothing else of interest in her past history except for tuberculosis in her mother, who is now a patient in the tuberculosis ward. The patient herself had had pleurisy several times in the past two years, and is now being observed for other evidences of tuberculosis, which as yet have not appeared.

Physical Examination.—On admission, the patient was an undernourished white female, with a temperature of 100°, a blood pressure of 112/60, and a rapid, regular, full pulse. She had a rather set expression to her face. Her jaw was held tense, almost completely closed, with the corners of the mouth drawn slightly back and upwards. Slight wrinkling of the forehead was present. Her upper dental plate could not be removed. There was moderate neck rigidity with pain in the upper spine on attempted flexion of the neck. Her biceps, triceps, patellar and achilles reflexes were all equal and markedly hyperactive. Ankle clonus was present bilaterally. Kernig's sign was positive. Babinski's sign was negative. The previously mentioned sliver was present, lodged in the epidermis of the fifth finger of her right hand. There was no evidence of infection or local reaction. The foul-smelling vaginal discharge was noted, but pelvic examination revealed nothing excepting slight enlargement of the uterus. There were no other positive physical findings.

Laboratory Findings.—The urine was negative. The blood was negative except for a 4 plus Wassermann reaction. The spinal fluid on first examination showed a 4 plus Wassermann. Pressure varied greatly from time to time, and after administration of antitoxin the globulin content increased to 3 plus at one time, and the cell count, also variable, rose as high as 1,800 per cu. mm. Colloidal gold determinations showed a slight rise in the last four tubes. Culture of the spinal fluid showed no growth.

Treatment.—Nutrition was maintained by nasal tube feedings of eggs, milk and sugar two or three times daily. The sedatives used were morphine in quarter grain doses every four hours for the first few days, and chloral hydrate in doses of from 20 to 30 grs. with each nasal feeding. The specific treatment consisted of massive doses of tetanus antitoxin. Spinal drainage followed by intraspinal injection of 20,000 units of the antitoxin was done daily for ten days. Intravenous injection of 10,000 units was done daily for seven days, and a total of 14,000 units was given intramuscularly about every third day. Thus, a total of 272,000 units of antitoxin was administered over a ten-day period.

Progress.—During the first forty-eight hours in the hospital the patient ran a progressively down-hill course. Her jaws became completely locked, the sardonic grin more marked, and her lips and nails became definitely cyanotic. All the muscles of her body were involved in a generalized hypertonicity. Her spine assumed the position of opisthotonos, her neck became very rigid, and her arms and legs became almost completely paralyzed, manifesting a lead-pipe spasticity. Her fingers remained extended and spastic. There were frequent jerkings and twitchings of all the muscles, especially those of the spine, causing considerable pain. This symptom was fairly well controlled by morphine and chloral. The reflexes became more hyperactive, almost to the point of clonus. However, from the third to the seventh day after her admission, improvement was slow but progressive, and at the end of a week the general rigidity had greatly diminished. The patient was then able to open her jaw sufficiently to allow the removal of her upper dental plate, and was able to swallow a liquid diet fairly well. Jerking and twitching with pain in the spine were still present at times, but of lessened severity. The neck rigidity and opisthotonos had improved greatly. All these symptoms and signs gradually improved until on the 22nd of May, 18 days after admission, the patient was back to a practically normal condition, with the exception of weakness and a slight stiffness of her knees and elbows on extreme extension. There was no evidence of residual paralysis, and her jaw could be opened to a practically normal degree. There was nothing characteristic about the temperature, which varied from 100° to 104°, and persisted for twelve days.

Complications.—On the seventh and eighth days after admission the patient complained of abdominal cramps, which were relieved in both instances by atropin and enemata. On the ninth day after admission she complained of pain in her right lower chest, worse on deep inspiration. A definite friction rub was heard over this area, with diminished breath sounds. This cleared up in twenty-four hours with no special treatment. On the tenth and eleventh days after admission she developed a toxic psychosis, with very vivid delusions of persecution. She made a complete recovery from this psychosis within forty-eight hours. Convalescence was otherwise uneventful.

Discussion.—We believe the induced abortion was the etiological factor in this case, because, with the exception of the sliver, no other possible portal of entry could be discovered, either by physical examination or from the history. We feel that the short time interval between this sliver injury and the onset of symptoms (three days) as well as the insignificance of the injury ruled it out, whereas the time interval between the abortion and the onset of symptoms (fourteen days) is a reasonable incubation period. Also, the evidences of infection in the uterus lent credence to this view.

We believe the chief point of interest in this case was the fact that cure was effected by massive doses of tetanus antitoxin alone, without the use of other advocated curative measures.

Ancker Hospital,
Saint Paul.

BISMUTHOIDOL NOT ACCEPTABLE FOR N.N.R.

The Council on Pharmacy and Chemistry reports that in 1926 Les Laboratoires Robin, Paris, France, requested acceptance of Bismuthoidol, which was stated to be colloidal bismuth in isotonic solution. The product is distributed in the United States by E. Fougera & Co., New York. The Council examined the submitted evidence and informed the proprietors that it was insufficient to establish the claims advanced for the product. In 1930 E. Fougera & Co. again requested consideration of Bismuthoidol. The Council examined the further evidence which was submitted and informed E. Fougera & Co. that Bismuthoidol is at present unacceptable for New and Non-official Remedies because the submitted advertising shows that, if accepted, its acceptance would be used to advertise unaccepted products and because the claims made for the product are unwarranted. The Council's report calls attention to the fact that, while the Council holds the intravenous administration of bismuth preparations unsafe, Bismuthoidol is used intravenously. (Jour. A. M. A., June 20, 1931, p. 2104.)

USE OF SALINIZED WATER IN INDUSTRY

At the present time salines are regarded as preferable to dextrose in the prevention and treatment of factory cramps due to excessive loss of fluid and salines through sweating. Both prevention and treatment of cramps are well abetted by the intake of dilute saline solutions to compensate for loss through sweating. It is, however, undesirable that tablets of salts be taken into the body as such. It is better that the entire water supply be treated with salt to the extent of 1 per cent. A strength from 0.3 to 0.5 per cent, being more palatable, may lead to more extensive use, especially if kept at a temperature from 47 to 52 F. (Jour. A. M. A., June 13, 1931, p. 2055.)

PRESIDENT'S LETTER

I HAVE been wondering what impression Will Rogers' statement, that the American mother would be safer in India than she is here at home, has made on the American public.

Such bombshells as this are thrown at us every once in a while. They may be facts and they may not. But a statement from Will Rogers is likely to be very extensively read and very extensively believed anyhow.

That being the case, I feel very strongly that the State Association, through the American Medical Association, should investigate the matter carefully. It occurs to me that there may be a question of reliability of statistics in this comparison with Mother India. But we ought to know, anyhow, whether we are dealing with facts or dramatic rumors. We ought to know whether it is a fact, as rumor has it, that 16,000 mothers die in America in child-birth every year, 10,000 of whom, at the very least could have been saved.

If it is indeed a fact, then a grave responsibility rests upon the physician in active practise and not upon the physician alone. Surely ignorance of such fundamental laws of health and hygiene as are involved in seeking adequate prenatal care, is also the problem of the school, the church. I can see no reason why such education should not be included in our high school curricula. Neither we, the physicians, nor the educators, nor the clergy are doing all in our power to correct this sorry situation unless we are also doing everything in our power to educate that unfortunate 10,000 before it is too late. If we are not, then we must accept the just indignation of the public as no more than our due.

I am sure no conscientious physician feels other than keenly responsible for the welfare of his own clientele. He should extend that feeling of responsibility beyond the confines of his own group and his own town. He must see that his efforts do not cease until schools, churches, every agency of public welfare, are not only teaching the imperative necessity of prenatal care but teaching it properly and authoritatively. It is actually a disgrace to every intelligent American, no matter what his trade or his profession, that mothers should still be sacrificed to ignorance in this enlightened land.

Some good might be accomplished, I should think, if the local county medical society made an official point of the matter. An official message through the newspapers of each medical society territory to every mother in the territory should be effective. At any rate, the mothers cannot be urged too often through any means at our disposal to seek early care and advice from their family physicians.

L. Sogge

President
Minnesota State Medical Association.

THE DRUGGIST AND THE DOCTOR

An article on the unsatisfactory relations existing between the druggists and doctors entitled "Why Don't We Get Together?" in the July number of the *Northwestern Druggist* offers some food for thought. A number of criticisms of each profession by various members of the other profession form the subject material. As Sir Roger de Coverly was wont to say, "Much may be said on both sides."

We doubt whether the relations between the two professions are as strained as the article might lead one to suppose. The work of the two professions is supplementary, with the same objective—the patient's interest. Incidentally both groups have to earn a living. Isn't it true that most of us frequently consult some acquaintance in the other profession for information regarding the compounding of prescriptions—a subject that is their specialty? We admittedly know less about pharmacy than our predecessors. The same may be said of the druggists. How many of them are expert pharmacists?

While the physician is admittedly poorly informed on the subject of pharmacy, the pharmacist must in honesty admit his limitations in therapeutics. Counter prescribing by the druggist is surely against the public good, is likely to be useless (another item in the unnecessarily high cost of sickness), and in some instances distinctly harmful. The subject must be viewed, however, with a certain amount of common sense. Certain remedies are and should be sold directly to the public by the druggist. Suggestions on the part of the druggist that the purchaser see a physician for trivial ailments would suggest collusion between the two professions. On the other hand, the medical profession which has declared it unethical for its members to prescribe remedies of unknown composition expects the druggist to step in line.

The evils of self medication will always be with us and will have to be combated by various methods. The practice forms an important item in the cost of sickness which might be prevented. Physicians have come to rely less and less on medicines, so many of which are useless. Most of us limit our prescriptions to the small list of truly efficacious remedies. Incidentally the old time shotgun prescription being a thing of the past the incompatibility of drugs has come to be a matter of minor importance.

It will always be necessary continually to emphasize the foolishness of self medication in all publicity activities. All but a few of the more enlightened newspapers are still offenders in their advertising of fake remedies and the air is full of nauseous fake health remedies. Doubtless the improvement already shown in some quarters will continue.

Substitution and the intentional incorrect filling of prescriptions is probably the most reprehensible sin on the part of the druggist. The physician is entitled to feel absolute confidence that his patient is getting what his prescription indicated.

We have frequently had a great deal of sympathy for the druggist when he is called upon to fill prescriptions following a tour of the local medical profession by a detail man. New remedies of unproven value have to be stocked for perhaps a single prescription. The druggist feels he must charge enough for the prescription to reduce as much as possible what is likely to be a losing deal.

Drugs as well as the doctor's fee are generally considered an unnecessary expense by the laity and the average individual usually is alive to a charge of a few cents more for a prescription on the part of the uptown druggist, forgetting that he is forced to charge more because of a smaller volume of business, delivery service, et cetera. We know of only one wealthy druggist and, in this instance, only by hearsay. There probably are a few. Those who make a good income doubtless make it on side lines—everything from the postage stamp to the automobile tire.

After all, the solution of these difficulties lies in both groups playing the game according to the rules. It is simple enough for either group to gather instances of infringement by individuals in the other group. Honesty on both sides is all that is necessary.

TETANUS PREVENTION

The Fourth of July is past. So far we have seen no reports of deaths from tetanus following injuries from fireworks. The story of the prevention of tetanus deaths following the idiotic celebration of our national independence day is a fine example of what can be accomplished through specific serum inoculation and publicity. In 1903 there were 406 deaths from tetanus following Fourth of July injuries. This was reduced in 1904 to ninety-one and in 1913 to four. It would be grounds for malpractice if a physician failed to administer tetanus antitoxin following a Fourth of July injury. How about injuries the remaining 364 days in the year?

Unfortunately the results of the administration of tetanus antitoxin in the comparatively few cases of infected wounds encountered by the general practitioner are not striking. He never knows whether he has prevented the development of tetanus or not. One sad experience with an infected wound, and every infected patient receives the inoculation for a time at least.

Tetanus is a strange and subtil infection and strikes when one least expects it. The idea of the rusty nail's causing the infection has been put in the discard. We know that fertilized soil is the chief habitat of the tetanus bacillus. Penetrating wounds furnish the anaërobic soil for its growth. Whether the germ on the skin is driven into the wound or whether the wadding or piece of firecracker contain the germ is not clear. The anaërobic medium in the penetrating wound is probably the important consideration.

Experience during the World War with infected wounds on a large scale demonstrated conclusively the value of prophylactic tetanus inoculation. Occasionally tetanus has developed in spite of one inoculation and therefore a second dose or even weekly doses are recommended for safety.

The case of tetanus reported in this number of the journal is one of a patient that recovered. At the same hospital this year a fatal case occurred, the fatality resulting probably from an anaphylactic reaction. Another reported in the newspaper following a firecracker burn was determined to have been due to cerebral hemorrhages, possibly due to a coexisting encephalitis.

We know of another death from tetanus that occurred in Saint Paul in July in spite of one preventive inoculation and heard of a recent similar case in Saint Cloud.

When once tetanus has developed the treatment has to be rigorous and the mortality is high. Prevention is safer and easier but requires vigilance. It is very easy to become lax in this matter. Because of a seeming increase in the incidence of the infection attention is called to the importance of its prevention, by at least two inoculations at a week's interval.

OBITUARY

Dr. J. J. O'Hara

1868-1931

The death of Dr. J. J. O'Hara, Janesville, Minnesota, president of the Waseca County Medical Society for the year 1931, occurred at his home July 6, 1931. Death was caused by coronary thrombosis. Dr. O'Hara was sixty-three years of age at the time of his demise.

Dr. O'Hara was born February 8, 1868, at Edinburgh, Scotland, the son of Mr. and Mrs. James O'Hara. He came to Canada as a young man, and entered Queens University at Kingston, Ontario, from which institution he received his degree as a physician and surgeon in 1898. The same year he came to Alma City, where he engaged in the practice of medicine until a few years later, when he moved to Janesville.

Always active in civic matters, Dr. O'Hara has served for a number of years as president of the local library board, as officer of the county Red Cross organization and as president of the county medical association. He was a member of long standing in the Masonic order, the Modern Woodmen of America and the Royal Neighbors. He is survived by his wife and two sons, Bruce A. O'Hara, of West Allis, Wis., and D. M. O'Hara of Saint Paul.

Dr. L. A. Fritsche

1862-1931

Dr. L. A. Fritsche, veteran New Ulm physician and surgeon, died at his home June 18, 1931. Death followed an illness resulting from a collapse last November which occurred while Dr. Fritsche was making one of his closing speeches in his campaign for Congressman of the Second district, as farmer-labor candidate.

Dr. Fritsche was born on a farm in Lafayette township, Nicollet county, May 28, 1862. His parents, the late Mr. and Mrs. Frederick Fritsche, were prominent pioneer settlers of that community. After spending his boyhood on the farm, and finishing the rural school, Dr. Fritsche attended St. Peter High school, before entering the medical college of the University of Michigan, at Ann Arbor.

He was graduated from the medical school in 1887, the year Minnesota's medical practitioners' licensing statute became effective. Although not required to pass the Minnesota State Board of Medical Examiners, due to the fact that he had received his degree before the law went into effect, he decided to take the prescribed examination, passed it, and received the first license to be issued by the board.

Returning to New Ulm, Dr. Fritsche practiced his profession there for one and one-half years, and then went to Germany, to take a postgraduate course at the University of Berlin, which he completed in 1890. Thereupon he came back to New Ulm, and had since practiced medicine and surgery there, being the oldest resident physician, in years of service to the community, at the time of his death. Dr. Fritsche was the first in that section to employ aseptic and antiseptic surgery, and was one of the first surgeons in Minnesota to perform an appendectomy operation.

Dr. Fritsche was a member of the State Board of Medical Examiners from 1900 until 1902.

While Dr. Fritsche's practice was very extensive, he still found time to take a keen interest in political and civic affairs. He was first elected mayor of New Ulm in 1912, and served as chief executive for ten years.

While attending Berlin university, Dr. Fritsche was a member of the 10th International Medical Congress, which convened in that city in 1890, and presented two cases in the English language to the Gynecological section for Prof. Dr. Alfred Duehrssen. He served as health officer of New Ulm from 1891 to 1894, and held many other public offices of his town and county.

Dr. Fritsche was one of the organizers of the farmer-labor political movement in New Ulm, and his counsel was eagerly sought by the leaders of that party in Minnesota. He was a candidate for governor, under the farmer-labor banner, in the primary elections of 1924 and 1928, and was candidate of his party for congress from that district last fall. In 1922 he entered the race for the farmer-labor nomination for United States senator.

In the death of Dr. Fritsche, New Ulm and the state lose one of their foremost citizens, who was loved and respected by all who knew him. A pioneer physician, before the advent of the automobile and good roads, he cheerfully responded to calls for his services, not only from patients in New Ulm and immediate vicinity, but in a large radius, regardless of weather, winter and summer. He sacrificed much for those dependent upon him for medical aid.

Another exemplary characteristic was his readiness to help the needy, and he gave liberally to every worthy cause.

Dr. Fritsche's generosity was almost a fault. No one in need came to him in vain. He gave liberally of his means, but did so unostentatiously. He also contributed generously of his time and efforts to civic enterprises, never being too busy to do even more than his share toward furthering the welfare of his community and the state.

Dr. Fritsche was married in Berlin, Germany, June 14, 1890, to Miss Amalie Pfaender, daughter of the late Colonel and Mrs. William Pfaender, Sr., his surviving widow. To this union, seven children were born, two of whom preceded their father in death, namely, Alexander Frederick, who died in infancy, and Dr. William Fritsche, who passed away in 1923. The five living sons and daughters are: Mrs. H. W. Bond, White Plains, N. Y.; Drs. Albert and Carl Fritsche, who were associated with their father in the Fritsche clinic here; Miss Louise Fritsche, who recently received her degree as master of arts from Columbia University, New York; and Dr. Theodore Fritsche, interne at Letterman Army Hospital, San Francisco, Calif. There also are three grandchildren, as well the the following brothers and sisters: Mrs. William Mueller, St. Peter, and Emil and Otto Fritsche, Lafayette township.

A PAGE FORUM OF THE COMMITTEE ON PUBLIC HEALTH EDUCATION

A Doctor Talks to Social Workers

An important and much needed plea for better and closer coöperation of public health workers with the family physician was made in Minneapolis recently before the National Conference on Social Work by E. A. Meyerding, St. Paul, Secretary for the State Association.

At the moment Dr. Meyerding was speaking as the head of the Christmas Seal organization of Minnesota and his observations were not those of a representative of organized medicine but of an experienced public health worker addressing other public health workers and social service workers. The talk was therefore bound to be particularly effective—another instance, in fact, of the successful working of the unique liaison between public health agencies and organized medicine in our State.

Below are reprinted a few pertinent excerpts of the talk, which reached many conference delegates from all parts of the United States.

"Time was when we public health workers were content if one or maybe two medical men in the community interested themselves in our work. If the rest of the practicing medical profession seemed indifferent or antagonistic to the work, we took it as part of the inevitable state of things and did nothing.

"We know now that such a state of things is wholly unnecessary. We know, also, that we cannot now and never did accomplish anything of lasting worth that had not the approval and help of the family physician.

"It is well for us to remember, in the first place, in these days of long and intensive training for the practice of medicine, that we cannot hope to discover any other group engaged in health work with the knowledge and training possessed by this especially qualified class.

"Furthermore—and this is an angle of the question that needs great emphasis now and then—the lay worker must remember that the most indifferent and apparently under-qualified medical practitioner in an obscure country community is bound to know a good deal more about health in general and about his community in particular than the best informed and the most enthusiastic of lay health workers.

"Any state program such as ours, involving such projects as diphtheria inoculation or Mantoux tuberculin testing, is ended, so far as our active participation is concerned, when the few days of testing or clinics are past. If the medical men of the community have not already been persuaded of the value of the project, if their aid has not already been enlisted through the regular channels, both at the time of the clinics and after, then our own time and money and enthusiasm have been worse than wasted.

"We have found in the Minnesota Public Health Association that if our program is conservative and scientifically sound the medical men have been more than willing to accept and endorse it. As local distributor of health, the doctor has as much pride and interest in all local health movements as the lawyer or the hardware man or the grocer or the druggist or banker have in their special fields. The smaller the community the more justly the medical man may feel that he is, after all, the logical guide in these matters for his friends and neighbors.

"In any case our part as a semi-official health agency has been strictly education. The best that we can do to further the use of the Mantoux test, for instance, is to demonstrate it for the laity, for the public health official and for the doctor. We must show all of these how it works, what its benefits may be expected to be. If we fail to prove our point to the regular medical practitioner we have failed in the most important part of our program. Our work becomes a trivial fruitless business, something new to occupy field workers and annoy busy doctors—of no use at all in the fight against disease."

REPORTS AND ANNOUNCEMENTS OF SOCIETIES

MEDICAL BROADCAST FOR THE MONTH

The Minnesota State Medical Association Morning Health Service.

The Minnesota State Medical Association broadcasts weekly at 11:15 o'clock every Wednesday morning over Station WCCO, Minneapolis and Saint Paul (810 kilocycles or 370.2 meters).

Speaker: William A. O'Brien, M. D., Associate Professor of Pathology and Preventive Medicine, Medical School, University of Minnesota.

The program for the month of August will be as follows:

August 5—End-results of the Treatment of Overweight.

August 12—Mongolian Idiocy.

August 19—The Liver Treatment of Pernicious Anemia.

August 26—The Occupational Factor in Cancer.

SOUTHERN MINNESOTA MEDICAL ASSOCIATION

Through the kindness of Headmaster Charles W. Newhall the facilities of the Shattuck School have been turned over to the members of the Southern Minnesota Medical Association and their friends, for the annual meeting, which is to be held at Faribault in the Shattuck School on August 24.

PROGRAM

MORNING SESSION

8:00 A. M.—School for Feebleminded
- Demonstration of mental cases—J. M. Murdoch, M.D., and Staff

9:00 A. M.—Shattuck School
- Pediatric clinic—E. D. Anderson, M.D., Minneapolis
- X-ray demonstration—R. G. Allison, M.D., Minneapolis, and C. G. Sutherland, M.D., Rochester
- Varicose vein clinic—R. C. Logefeil, M.D., Minneapolis
- Demonstration of psychometric tests—Fred Kuhlman, M.D., Minneapolis (Director Division of Research of the Minnesota State Board of Control)
- Dermatologic clinic—P. A. O'Leary, M.D., and Staff, Rochester

11:00 A. M.
- Pathologic demonstration—H. E. Robertson, M.D., Rochester, and A. M. Snell, M.D., Rochester
- Hematology demonstration—F. J. Heck, M.D., Rochester, and C. H. Watkins, M.D., Rochester
- Unusual case reports—Discussion led by Moses Barron, M.D., Minneapolis
- Case of a large gall stone causing intestinal obstruction—B. J. Gallagher, M.D., Waseca
- Case of streptococcic septicemia with recovery—O. J. Swenson, M.D., Waseca
- Sarcoma of the jaw in a three-weeks' old infant, and albuminuria in pregnancy—C. C. Leck, M.D., Austin.
- Others to be announced later.

AFTERNOON SESSION

2:00 P. M.
- Normal and abnormal motility syndromes of the upper urinary tract with indications for drug and sympathectomy therapy—W. P. Herbst, M.D., Minneapolis
- Selection of patients for prostatectomy—Hugh Cabot, M.D., Rochester
- The injection treatment of hemorrhoids: some fallacies and complications—Walter Fansler, M.D., Minneapolis
- Carcinoma of the bronchus—P. P. Vinson, M.D., Rochester
- Analysis of 600 cases of spinal anesthesia—W. C. Stillwell, M.D., Mankato
- Paper—S. W. Harrington, M.D., Rochester
- Treatment of pneumonia—H. A. Reimann, M.D., Minneapolis
- And others

BANQUET

6:30 P. M.—Banquet Hall, Shumway Hall, Shattuck School
- President's address—J. T. Schlesselman, M.D., Mankato
- Address of welcome—C. W. Newhall, Headmaster, Shattuck School
- Remarks—W. A. Rohlf, M.D., Waverly, Iowa, (President, Iowa State Medical Association)
- Talk on Russia illustrated by movie films—T. L. Birnberg, M.D., St. Paul Amphitheater, Shumway Hall, Shattuck School

It has been suggested that possibly many members would like to come to Faribault on Sunday afternoon. There is an excellent golf course, tennis courts, and swimming pool which may be used on Sunday afternoon and any time Monday. Luncheon will be served at the Shattuck School, as will dinner, and there is ample space for parking.

NORTHERN MINNESOTA MEDICAL ASSOCIATION

A distinguished and varied program of scientific and social events has been arranged for the Northern Minnesota Medical Association meeting to be held at Hibbing, on Monday, September 14, 1931.

A trip into the open pit of the mine and a tea for Auxiliary members are among the events scheduled for the day.

Scientific sessions will be held at the Androy Hotel. The first will be a clinico-pathologic conference by Dr. M. M. Fischer, internist; Drs. G. L. Berdez, pathologist; Gage Clement and J. R. McNutt, roentgenologists, with discussions led by Dr. E. L. Tuohy, all of Duluth.

Dr. L. R. Gowan, Duluth, will read a paper on

"Multiple Sclerosis," and Dr. O. W. Rowe, Duluth, will talk on "Pediatrics."

Dr. D. C. Collins and Dr. John S. Lundy, Rochester, will talk respectively on "Peptic Ulcer" and "Modern Phases of Anesthesia." Dr. A. N. Snell, also of Rochester, will talk on "What the American Doctor Sees in Europe." Dr. Thomas Myers, of St. Paul, will talk on "Pathology of the Newborn" and Dr. W. H. Hengstler, also of St. Paul, on "Remote Effects of Head Injuries." Dr. N. O. Pearce, Minneapolis, will repeat the paper, with slides, on Medical Economics, which he gave at the State meeting in May.

Dr. M. S. Henderson, Rochester, President-Elect of the Minnesota State Medical Association, and a mining engineer recently returned to America from Russia, will appear on the evening program.

Dr. B. S. Adams, Hibbing, and Dr. E. K. Smith, of Duluth, are in charge of the program.

UPPER MISSISSIPPI SOCIETY

More than thirty physicians and their friends from various parts of the district attended the summer meeting of the Upper Mississippi Medical Society held at International Falls on Saturday, July 18, 1931.

An important Scientific program in the Masonic Hall at International Falls occupied the morning. A fish dinner at the Rainy Lake Hotel at Fort Frances, Ontario, and a delightful four hour boat excursion on Rainy Lake, with stops at some of the fine Rainy Lake summer estates, were on the day's schedule.

An intense interest on the part of everybody present in the affairs of the society and organized medicine in general and in the papers presented was an outstanding feature of the meeting. On the program were:

Dr. E. A. Meyerding, St. Paul, "What's Doing in Your State Medical Society"; Dr. P. F. Eckman, Duluth, "Secondary Anemias"; Dr. Donald Creevy, Minneapolis, "Prostatic Obstruction"; Dr. Karl Anderson, Minneapolis, "Treatment of Nephritis"; Dr. L. R. Gowan, Duluth, "Localization of Spinal Cord Tumors"; Dr. W. W. Lewis, St. Paul, "Inflammatory Infection of the Middle Ear"; Dr. Paul G. Bohman, Duluth, "Newer Methods of Diagnosis in Diseases of the Lung."

Many of those who attended remained in the North for several days to finish their vacations.

WABASHA COUNTY SOCIETY

The sixty-third annual meeting of the Wabasha County Medical Society was held at Lake City, Minnesota, Thursday, July 9, 1931.

The scientific program was carried out as published in the July number of MINNESOTA MEDICINE.

The following officers were elected to serve for the coming year: President, Dr. W. F. Wilson, Lake City; vice president, Dr. W. B. Stryker, Plainview; secretary-treasurer, Dr. Russell H. Frost, Wabasha; delegate to State Association, Dr. H. E. Bowers, Lake City; alternate, Dr. D. P. Dempsey, Kellogg; censor for three years, Dr. W. J. Cochrane, Lake City. The other censors are Dr. J. F. Bond, Wabasha, and Dr. J. A. Slocum, Plainview.

It was voted to hold the next annual meeting at Plainview. Dinner was served at the Hotel Lyon through the courtesy of the Lake City members of the Society was present to discuss with a similar committee twelve members and affiliates, four visiting physicians, two laymen, and the ladies accompanying.

Following the dinner and picture feature captivatingly presented by Dr. Thomas S. Roberts of the University, the ladies were given a boat ride on Lake Pepin.

A committee from the Winona County Medical Society was present to discuss with a similar committee from the Wabasha County Society the advisability of amalgamation of the two societies.

A resolution was drawn up favoring such merger, and is to be submitted to each member of the two societies for vote.

Following the address of Dr. E. C. Bayley, which stressed the necessity of pure milk as a preventive of several diseases, action was taken toward securing pasteurized milk for all places in the county not already afforded such supply.

In line with the present teaching regarding humidity as a health factor in winter heating, a newly devised and comparatively inexpensive humidifier was demonstrated to those in atendance.

The usual vote of thanks was tendered all those who had a part in the entertainment of the society.

W. F. WILSON, *Secretary.*

WOMEN'S AUXILIARY
Minnesota State Medical Association

President—Mrs. S. S. Hesselgrave, St. Paul
Chairman Press and Publicity—Mrs. E. A. Meyerding, St. Paul
Editor—Mrs. A. A. Passer, Olivia

Two Minnesota women were elected to national offices in the Women's Auxiliary of the American Medical Association at the meeting in Philadelphia, which was held from June 8 to June 12: Mrs. James Blake, Hopkins, Vice-President; and Mrs. Sherman S. Hesselgrave, Saint Paul, Recording Secretary.

LYON-LINCOLN COUNTY AUXILIARY

Mrs. S. S. Hesselgrave, St. Paul, recently elected recording secretary of the Women's Auxiliary to the American Medical Association and former president of the Women's Auxiliary to the Minnesota State Medical Association, assisted in the organization of the Lyon-Lincoln County Medical Society Auxiliary at Marshall, Minnesota, on June 29, 1931.

The occasion was a joint dinner between medical society members and the new women's group. Following the dinner the two groups held separate meetings. Mrs. Hesselgrave was introduced to the women's meeting by Dr. W. G. Workman, Tracy, Minnesota. Dr. E. A. Meyerding, St. Paul, Secretary of the State

Association, also talked to the women on "The Uses of the Auxiliary."

The following officers of the new organization were elected: Mrs. W. W. Yaeger, Ivanhoe, President; Mrs. Peter Hermanson, Hendricks, Vice-President; Mrs. W. G. Workman, Tracy, Secretary, and Mrs. W. H. Valentine, Tracy, Treasurer.

NEW AND NON-OFFICIAL REMEDIES

The following products have been accepted by the Council on Pharmacy and Chemistry of the American Medical Association for inclusion in New and Non-official Remedies:

Syrup No. 112 Ephedrine Hydrochloride.—It contains ephedrine hydrochloride-Lilly (New and Non-official Remedies, 1931, p. 175), 0.22 Gm., in 100 c.c. (1 grain per fluidounce), and alcohol, 12 per cent. Eli Lilly & Co., Indianapolis, Ind.

Quiniobine.—Quinine bismuth iodide rendered soluble in olive oil by means of lecithin. Each c.c. contains 0.03 Gm. of bismuth, 0.03 Gm. of quinine, 0.075 Gm. of iodine, and 0.22 Gm. of lecithin. Quiniobine is proposed as a means of obtaining the systemic effects of bismuth in the treatment of syphilis (New and Non-official Remedies, 1931, p. 94). It is claimed that, since in Quiniobine the quinine bismuth iodide is soluble, the injections are usually only slightly painful and the dosage is more accurate than with suspensions of quinine bismuth iodide. It is supplied also in the form of 2 c.c. ampules. Spicer & Co., Glendale, Calif. (Jour. A. M. A., June 6, 1931, p. 1953.)

Calcium Gluconate.—It contains calcium equivalent to not less than 12.4 nor more than 12.8 per cent of calcium oxide. Calcium gluconate is used to obtain the therapeutic effects of calcium. It is more palatable than calcium chloride for oral administration and for hypodermic or intramuscular use is non-irritant.

Calcium Gluconate-Pfizer.—A brand of calcium gluconate-N.N.R. Chas. Pfizer & Co., Inc., Brooklyn, N. Y.

Concentrated Pollen Antigens-Lederle.—Liquids obtained by extracting the protein from the pollen of plants with a liquid consisting of 67 per cent of glycerin and 33 per cent of a buffered saline solution. For a discussion of the actions and uses, see Allergic Protein Preparations, New and Non-official Remedies, 1931, p. 23. Concentrated pollen antigens-Lederle are marketed in packages of fifteen syringes containing increasing dosages; also in supplementary treatment packages of five syringes. The following product has been accepted: Concentrated Pollen Antigen (Lederle) Ragweed Combined (Common and Giant Ragweed in equal parts). Lederle Laboratories, Inc., Pearl River, N. Y. (Jour. A. M. A., June 13, 1931, p. 2036.)

FOODS

The following products have been accepted by the Committee on Foods of the Council on Pharmacy and Chemistry of the American Medical Association for inclusion in Accepted Foods:

SMACO (206) Powdered Whole Milk (S. M. A. Corporation, Cleveland).—A powdered spray-dried whole milk hermetically sealed in tins in an atmosphere of nitrogen. It is claimed by the manufacturer that each 12 ounce can will make 2.8 quarts of liquid milk of normal strength.

Firch's Ma Made Bread (Sliced and Unsliced) (Firch Baking Company, Inc., Erie, Pa.).—A white bread (sliced and unsliced) made by the sponge dough method. (Jour. A. M. A., June 6, 1931, p. 1953.)

Torex (Concentrated Beef Bouillon) (International Products Corporation, New York City).—A semifluid mixture of beef extract, salt, vegetable extract, starch and powdered white pepper and onion; packed in block-tin tubes. It is claimed that this product dissolves instantly in hot water, that it permits the quick preparation of a warm drink for the home and camp table and that it is adapted for seasoning gravies, stews, etc.

Bowey's Hot Chocolate Powder (Bowey's Inc., Chicago).—A mixture in powdered form of chocolate liquor, cane sugar and skim milk flavored with vanilla extract. It is claimed that this product makes a wholesome and delicious beverage of high caloric value which can be used in the preparation of delicious desserts.

Libby's Sterilized Unsweetened Evaporated Milk (Libby, McNeil and Libby, Chicago).—An unsweetened evaporated milk. It is claimed that this product approximates ordinary milk when diluted with an equal volume of water. It is proposed for use in infant feeding and may be used in cooking and baking as is ordinary milk. (Jour. A. M. A., June 13, 1931, p. 2037.)

Merrell-Soule Powdered Protein Milk (Merrell-Soule Co., Inc., New York City).—A powdered food made from milk; higher in protein and lactic acid and lower in lactose than dry whole milk. It is claimed that when restored to liquid form with water it closely approximates Finkelstein's protein milk formula. It is said to be indicated in cases of dyspepsia, alimentary intoxication, marasmus and celiac diseases.

Mead's Powdered Lactic Acid Milk Noncurdling No. 2 Plain (Mead Johnson & Co., Evansville, Ind.).—A powdered, spray-dried homogenized milk containing added lactic acid. It is claimed that the powder may be readily mixed with cool or hot water to form a fine suspension. The mixture may be boiled without curdling or change of color or taste. It is recommended for infant feeding.

Paul's Redi-Sliced Bread (Paul's Baking Corporation, Chicago).—A white bread made by the sponge dough method, in sliced loaf form. It is claimed to be a bread of good quality. (Jour. A. M. A., June 20, 1931, p. 2104.)

Saylor's Hom-Aid Bread (Saylor's Bakery, Inc., Tamaqua Heights, Tamaqua, Pa.).—A white bread made by the sponge dough method. It is claimed to be a bread of good quality.

Kwality Twin Loaf Bread (Kwality Baking Company, Champaign, Ill.).—A white twin-loaf bread made by the sponge dough method. It is claimed to be a bread of good quality. (Jour. A. M. A., June 27, 1931, p. 2197.)

CONSULTATION BUREAU

WM. A. O'BRIEN, M.D., *Director*
Minnesota State Medical Association
11 West Summit Avenue
Saint Paul, Minnesota

1. *Question.*—A young man, 23 years of age, college graduate, teaches school in winter and works on a farm in summertime. He recently had a complete examination at a clinic and a diagnosis of recurrent hemorrhages of the right eye into the vitreous with retinitis proliferans was made; the cause probably being tuberculosis. General examination, including an X-ray of the chest, is essentially negative. Had a very markedly positive tuberculin reaction but appears to be in excellent physical condition.

Vision is normal in both eyes. The right fundus examination shows fine floating opacities in the vitreous. The nasal half of the disc is obscured by a thin vascularized membrane of connective tissue extending two or three disc diameters above and below the disc and also into the vitreous. There are two small linear hemorrhages and a small area of proliferation about the periphery of the fundus. The fundus examination of the left eye is negative.

1. Is it probable that this condition will go on to blindness, and are there any definite measures that might prevent blindness?

2. In addition to hygienic measures tending to build up natural resistance, including ultraviolet irradiation, high vitamin diet and cod liver oil, is the gradually increasing dosage of old tuberculin considered good treatment? Should the patient derive immediate benefit from the same, or must it be continued over a period of several years?

3. In the matter of this man doing farm work in the summer, should any restrictions be placed on strenuous or severe work? Is it likely that hard work might increase the hemorrhages into the eye?

4. Are there any other therapeutic measures that might be used, such as the non-specific foreign protein injections?

Answer.—1. The tendency is for this condition to recur, with progressive loss of vision. It is probable that eventually the entire sight of the affected eye will be lost.

2. Systemic measures are very important, and you have outlined very well those which should be included in the treatment. Old tuberculin is not recommended, although used by some ophthalmologists. The tendency for reaction to occur is too great and those who use it are probably in the minority. It is not recommended for your patient.

3. Farm work, especially the more strenuous part, is not indicated. He should be advised to try some other summer occupation.

4. Boiled milk injections should be given. Inject from 10 to 15 c.c. of boiled milk, intramuscularly. Before you do this, take the leukocyte count and follow it at definite intervals, say every two days thereafter. When the count returns to normal, give a second injection. Three or four such injections should be given, followed by a rest for a month or so and then the treatment continued. In any event, the prognosis for complete preservation of vision is not good.

2. *Question.* Carpenter, 65 years, consulted me not long ago because of pains in various parts of the body and regurgitation of mucus in the morning. He has been ill for about a year. The pains are located chiefly in the muscles of the extremities and in the bones of the lower back region. They come and go, but are severe enough to keep him awake at night. He never vomits food, but brings up slime. When this material is out of the way, he is able to eat. Appetite is poor and he is constipated. There has been apparent marked weight loss in the past year. About three months ago he had a spell which was called a "stroke" by his physician. At that time his speech became indistinct and his tongue protruded to one side. No other paralysis noted. Speech difficulty partially improved. Slight unproductive cough and generalized chest pain for the past year. For several years he has had difficulty in urination. The stream became slower and nocturia developed. Physical examination is as follows: Blood pressure 130/70. Pulse 92. Temperature 97.8. The appearance is cachectic, tongue protrudes definitely to right side. No chest râles. There is definite widening of the upper sternal dullness, loud booming first tone at apex. No abdominal masses. Definite tenderness to percussion over sacrum. Rectal examination shows prostate to be only moderately enlarged, but there are a few small, hard nodules present, especially in the mid-portion. The knee and ankle reflexes are absent on the left. The upper extremity reflexes are present and qual. Hemoglobin 76 per cent, leukocyte count 11,600. Urine negative. Gastrointestinal X-ray study negative. X-ray of the chest, skull, pelvis and lumbar spine show hazy, punched-out areas in the bone and new bone formation. There are, also, definite soft shadows in the lungs. May we have your opinion in this case?

Answer.—The lesions in the lungs and bones are metastatic tumor deposits, and are both of the osteoclastic and osteoblastic types. From the X-ray standpoint alone, the diagnosis is metastatic carcinoma, probably from a tumor in the prostate gland. Multiple myeloma must also be considered, but the chest findings are against this diagnosis. Other metastatic tumors may show a similar picture, *e.g.,* a silent hypernephroma cannot be ruled out. From your description of the condition of the prostate it is most likely the source of metastasis. If the pain is severe, deep X-ray treatment is very helpful. While it may not influence the course of the disease it does make the patient feel better. Unless signs of urinary obstruction develop, no prostatic treatment is indicated. If obstruction takes place, a cystotomy can be done. Carcinoma of the prostate frequently acts like your description of this patient. The outlook is unfavorable, but the disease may progress rather slowly. The question of metastatic brain tumor as a cause of the stroke should also be considered. If the lesions in the brain are multiple tumor deposits, a diffuse reaction, chiefly inflammatory, resembling encephalitis, may be observed. The possibility of this development is strengthened by a personality change. It is most probable that the brain lesion is an accident and unrelated to the malignant condition.

OF GENERAL INTEREST

Dr. Arthur R. Kintner has moved from Rochester, Minnesota, where he was associated with the Mayo Clinic, to 1004 Central Avenue, Nebraska City, Nebraska.

Dr. and Mrs. Myron O. Henry have returned from Europe, where Dr. Henry spent three and one-half months in various clinics. He attended the meeting of the German Surgical Society in Berlin, the French Orthopedic Society at Berck-Plage, and also the British Orthopedic Society at Aberdeen, Scotland.

Dr. William Harold Ford, who is a graduate of the University of Minnesota, class of 1931, and who completed his Interneship at Ancker Hospital, Saint Paul, July 1st, has opened an office at 5161 Bloomington Avenue South, Minneapolis, for the general practice of medicine and surgery.

Members of the Association are urgently requested o look among their old papers and into the local medcal archives for the transactions of the Minnesota State Medical Association of the years 1865, 1887 and 1888. These papers are missing from the otherwise complete documentary history of the Association, and the state office will be greatly obliged to anyone who can supply hem.

Dr. and Mrs. C. J. Plonske of Faribault recently reurned from an extended tour by auto through the outheastern and eastern states, returning by way of Montreal. Attendance at the American Medical Assoiation meeting in Philadelphia was included in the trip. Dr. and Mrs. Plonske were accompanied by their daugher, Marion, and by Mrs. Plonske's father, Mr. F. H. Clarke of Minneapolis.

Dr. F. S. Warren, who discontinued practice in Fariault last fall, upon the occasion of a visit to Faribault n June with his wife and daughter, tendered a dinner o the physicians and nurses of the city. Dr. Warren ave an interesting account of his recent automobile trip o Florida, and numerous humorous and interesting peeches by those in attendance rendered the occasion most enjoyable. Dr. Warren left early in July for a our of the West.

Among summer epidemics of interest to the doctor in Minnesota this year, is an unusual outbreak of malractice suits.

The most effective protection against this epidemic s malpractice insurance carried by every member of he Minnesota State Medical Association. Such insurance may be obtained in the Aetna through our group policy as well as in several other good companies.

By all means, see that your malpractice policy has not lapsed. Remember also that what you say about your fellow practitioner may well start a malpractice suit.

Twenty-one out of 42 reports from probate judges in Minnesota counties indicate that officials are wholly in favor of organized medicine and eager to coöperate with its membership.

This desirable state of things is revealed in the interesting reports that are coming in to the state office these days following the bestowal through members in the county seats of the 1931 rosters of the association upon all county judges of probate in the state.

Of the other 21 reported, only four seemed to the members concerned to be definitely indifferent or uninterested in the state association and organized medicine in general.

Many enthusiastic statements were quoted from the 21 friendly judges by reporting members.

"Thank you. That is fine! said the Judge," reports the Stillwater member. "He thinks an M.D. not belonging to a county society is like a lawyer not belonging to the bar association and NO GOOD."

Other emphaticallly friendly officials were discovered in Detroit Lakes, St. James, Windom, Owatonna, Crookston, Little Falls, St. Cloud, Chaska, Wheaton, Ortonville, Glencoe, Cambridge, New Ulm, Marshall, Two Harbors and Worthington.

Several judges in the various counties were not approached at all, mainly for the reason that, all of the physicians in the county being members of the association, the members felt sufficiently assured of official cooperation anyway.

Two judges were reported in their dotage as a sufficient reason for lack of active interest in the matter. Another was rather astonishingly quoted as surprised to know that there was such a thing as a medical organization. Such a thing as expressing himself adverse to organized medicine was beyond the scope of his comprehension.

The following, who have been serving as internes at the Ancker Hospital, Saint Paul, the past year, are listed with their present positions and locations:

Dr. William R. Yeager is in general practice at Parkersburg, W. Va.

Dr. Waldemar G. Johanson is resident on the Receiving and Medical services at Ancker Hospital.

Drs. John P. Burgess, Viktor O. Wilson, and Alfred G. Ouellette are residents at the Children's Memorial Hospital, Chicago, Ill.

Dr. Harvey J. Brekke is resident at St. Luke's Hospital, Saint Paul.

Dr. W. Harold Ford is in general practice at 5155 Bloomington Ave. So., Minneapolis.

Dr. Thomas A. Starkey is a Fellow in medicine at the Mayo Clinic, Rochester.

Dr. Morris Greenberg is in general practice in Saint Paul.

Dr. William H. Lamberson is doing post-graduate work in otolaryngology at the University of Pennsylvania, Philadelphia.

Dr. J. Marshall Neely is resident pathologist at the Ancker Hospital, Saint Paul.

Dr. Harold L. Bolender is resident at the Midway Hospital, Saint Paul.

Dr. Richard S. Rodgers is a resident in Medicine at the Minneapolis General Hospital.

Dr. O. Harold Muus is associated with the Engstad Clinic, Grand Forks, N. D.

Dr. Willis M. Duryea is resident in pediatrics at the Abbott Hospital, Minneapolis.

Dr. Charles H. Slocumb is a Fellow in medicine at the Mayo Clinic.

Dr. Roy L. Robertson is in general practice at Mill Valley, California, with Dr. George Landrock.

Dr. William L. Pratt is resident on the receiving and medical services at Ancker Hospital.

Dr. George L. Shivers is doing post-graduate work at the University of Minnesota and the Mayo Clinic.

Dr. Cecil A. Warren, who has been the resident on the surgical service at the Ancker Hospital, is now in general practice at 373 New Lowry Medical Arts Bldg., Saint Paul.

Dr. J. Chester Ogden is now resident at Bethesda Hospital, St. Paul.

Dr. Arthur L. Osborn, who has been resident urologist at Ancker Hospital, is specializing in genito-urinary diseases in Kansas City, Mo.

Dr. Merle O. Thoreson, who has been resident on the medicine-receiving service at Ancker Hospital, is now resident in surgery at the same hospital.

Dr. C. Henning Mattson, who has been resident on the medicine-receiving service at Ancker Hospital, is now affiliated in general practice with Dr. Olof I. Sohlberg, 564 Lowry Medical Arts Bldg., Saint Paul.

STATEMENT REGARDING THE DISCOVERY OF THE DEAFENED PRE-SCHOOL CHILD ISSUED BY THE HEALTH COUNCIL OF MINNEAPOLIS

Population centers in which work is being done for the discovery of deafened pre-school children have been notably fruitful of results. We feel sure that in this respect Minneapolis is not an exception to the general rule. Many such children are discoverable and oftentimes remediable.

We have found, and we have been repeatedly admonished by other observers, that it takes *positive* inquiry to bring out the facts of such deafening in many cases; that parents are often careless themselves in noting the loss of hearing in their young children; and that if they do discover such loss they are frequently inclined to conceal the fact of the existence of such a handicap.

They are apt to think, too, that nothing can be done about it, when as a matter of fact very much can be done in these early years, when body and mind are still in the making; when the consequences of the diseases which cause deafening are most readily overcome by the otologist; when hearing and voice can be most readily trained; when lip-reading can be very easily taught to the young child and even by the interested mother.

We have already invited your coöperation in a joint effort being made by The Health Council, the Minneapolis League for the Hard of Hearing, and the Health and Social Agencies of the City, to find and to help these deafened little ones who, left alone, will, in a very large majority of cases, grow worse and will lay the foundation in childhood years for the development of adult deafness in days to come.

Will you not give us welcome further aid in this discovery, by teaching your health and relief workers the technic of search in the home, the family, the day and the nursery schools and the kindergarten? Will you not promptly advise the Executive Secretary of the Minneapolis League for the Hard of Hearing, in the Plaza Hotel, of your findings? She will do the rest, with the help of her co-workers, and the otologists, lip-readers and voice culturists. The results will be the relief of the young deafened children of today; the carrying-forward of the retarded children of the present and of the future; the saving of hearing impairment and its limitations among the adults of the near future.

Physicians, public health nurses, and teachers are also invited to aid by the reference of any such deafened children of pre-school age, who may be guided to the care of the otologist, and to the lip-reading teacher, and to the voice-trainer.

THE EDITOR'S SONG

If you have a tale to tell,
  Boil it down!
Write it out and write it well,
Being careful how you spell;
Send the kernel, keep the shell;
  Boil it down! Boil it down!

Then, when all the job is done,
  Boil it down!
If you want to share our fun,
Know just how a paper's run,
Day by day from sun to sun,
  Boil it down! Boil it down!

When there's not a word to spare
  Boil it down! Boil it down!
Heave a sigh and lift a prayer,
Stamp your foot and tear your hair,
Then begin again with care—
  Boil it down! Boil it down!

When, all done, you send it in,
  We'll boil it down.
Where you end there we begin;
This is our besetting sin;
With a scowl or with a grin,
  We'll boil it down; boil it down.

ROCEEDINGS OF THE MINNESOTA ACADEMY OF MEDICINE

Meeting of May 13, 1931

The regular monthly meeting of the Minnesota ademy of Medicine was held at the Town and untry Club, Saint Paul, on Wednesday evening, ıy 13, 1931. Dinner preceded the meeting, which s called to order by the President, Dr. J. S. Gilfil- , at 8 P. M.

There were forty-eight members and four guests sent.

Minutes of the April meeting were read and ap- ved.

Dr. H. L. Ulrich read the Necrology Committee's morial to Dr. Theodor Bratrud.

THEODOR BRATRUD, born in 1873, raised and educated Minnesota, a son of the "Giants in the Earth," car- d on the Viking spirit. Into the wheat fields of rthern Minnesota he brought the knowledge of the ert, the kindness of the great, the humility and un- standing of the prairies. His clinic was a haven of nfort and salvation to the afflicted of three states. eodor Bratrud in his diverse parts might have been prototype of the doctor in Sinclair Lewis' "Main eet"; in Ian Maclaren's "Beside the Bonnie Briar sh"; in Joseph Collins' "The Doctor Looks at Lit- ture." In his passing, one of the intrepid spirits of s state has unfurled his banner in its legendary halls. poet describes him in these lines:

"A simple man, yet none in all the land
More great. For he was ever found apart
Where beds of human suffering grimly stand;
And there, with soul alert, he lived his art—
The tender gift of healing in his hand
And God's sweet law of service in his heart."

We, the members of the Academy of Medicine, con- res of Theodor Bratrud, thus pay tribute to his mory.

We further move that a copy of this be spread on minutes of the Society and a copy be sent to his ter, Miss Luela Bratrud of Thief River Falls, Min- ota.

(Signed) F. E. BURCH,
A. SCHWYZER,
H. L. ULRICH, *Chairman.*

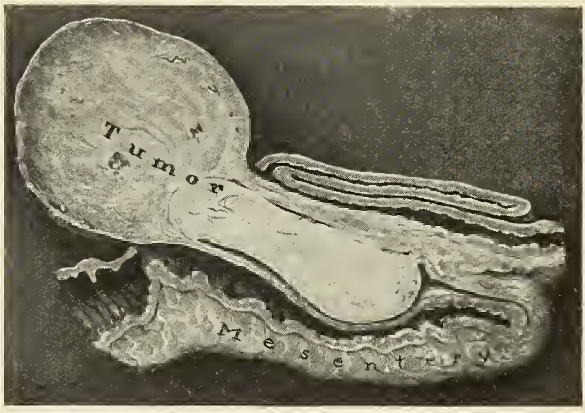
The scientific meeting was as follows:

DR. A. W. IDE (St. Paul) reported the following e:

The patient, a married woman 41 years old, was first n April 27, 1931, on account of acute abdominal dis- ess. This patient had had six children who are all liv- and well. She had had no previous illnesses; nei- r had she had any injuries. Four years ago she had abdominal operation elsewhere. The uterus was noved supravaginally on account of uterine bleed- . Her recovery from this operation was uneventful. Five weeks ago the present trouble began. There s abdominal distress with some tendency to nausea. There was obstinate constipation which gradually became worse. There was not a complete obstruction but the amount of stool passed was small and there was some blood.

When we first saw the patient she was having rather acute abdominal pain, evidently due to obstruction of the bowel. The exact nature of the obstruction could not be determined, but in view of her previous abdominal operation it was thought possible that the obstruction was due to adhesions resulting from this operation. The obstruction was evidently of the chronic type but apparently it was becoming complete.

On April 29, two days after the patient was first seen, an abdominal operation was done. Under ethylene anesthetic the peritoneal cavity was opened through the old scar. In doing so a loop of markedly distended bowel protruded through the wound. Intraperitoneal examination revealed a mass in the ascending colon which had the feel of a circumscribed tumor. Further examination revealed that there was an intussusception of the ileum into the large bowel. The loop inside of the bowel was hard and felt like a neoplasm of some kind. A considerable portion of the ileum was reduced but one loop could not be freed. A resection of fourteen inches of small bowel, including the mass, was done. About four inches of the ileum proximal to the ileocecal valve was left. This was turned in as a blind stump and a side-to-side anastomosis was made between the ileum proximal to the tumor and the cecum.



Artist's drawing of specimen removed at operation. Note intussusception of small bowel with tumor. The growth bulged completely through the bowel wall during the operation.

The patient made an uneventful recovery from the operation except for a mild wound infection. Now, fourteen days after her operation, she is sitting up and will be able to leave the hospital in a few days.

Intussusception in the adult is somewhat rare. In a monograph based on 400 cases collected from the London City Hospital by Perrin and Lindsay, the following figures are given: approximately 70 per cent of these intussusceptions occurred during the first twelve months of life; 10 per cent during the second twelve months. In other words, 80 per cent of the cases of intussusception occur during the first two years of life, 15 per cent occur between the ages of two years and fourteen years, and 5 per cent occur after fourteen years.

Elliott and Corscaden analyzed 300 cases of intussusception in adults. They observe that 100 of these cases, or 33⅓ per cent, were due to tumors of the bowel. Out of this 100 cases, 40 of these tumors were malignant and 60 were benign. You will observe from the specimen that this intussusception was due to a tumor.

Microscopic section of this tumor shows the surface to be covered by a thin layer of epithelium, evidently a remnant of the mucous membrane. An occasional mucous gland is seen near the surface. The rest of the tumor consists of spindle-shaped cells with an abundant mucinous intercellular substance. The diagnosis is myxoma. There are no mitotic figures and no areas of rapid growth, so the histological interpretation is *benign myxoma*.

Tumors of this type do not recur when completely excised. However, they have a notable tendency to local infiltration.

Dr. A. E. Benjamin (Minneapolis) reported the following case:

I wish to present a report of a case of unusually large encysted bladder calculi with enlarged prostate, hemorrhages and loss of weight.

The patient is a widower, retired farmer, 71 years of age, 5 feet 4¾ inches tall, and weighs 106 pounds. He has had very good health, with the exception of three attacks of pneumonia and rheumatism. He has had no injuries or operations. His family history is essentially negative.

About two years ago he began having pain through the bladder region, with dysuria, some frequency, and at times passed a good deal of blood, specially upon exertion. He had considerable gastrointestinal symptoms with extreme constipation, loss of appetite and weight, and he also complained of backache. Eight weeks ago he began having severe attacks of pain, with vomiting and difficulty in emptying the bladder. A diagnosis of cancer had been made.

The throat and tonsils were red, tongue slightly coated. His heart was dropped somewhat but there was no irregularity. The lungs were negative. He had a full lower abdomen with prolapse of the stomach and intestines, and a weak left inguinal ring. The prostate was considerably enlarged; he had a few hemorrhoids and moderate varicose veins of the legs. His blood pressure was 166/76, temperature 98.6°, pulse 80, respirations 20. He habitually had from 500 to 800 c.c. residual urine which contained a slight trace of albumin.

X-ray films of the pelvis and sound revealed two large stones in the bladder.

An operation was performed under spinal anesthesia. There was one stone 2¼″ × 1¾″ × 1¾″ encysted back of the prostate and difficult to dislodge. The smaller stone 1¾″ × 1¼″ × 1¼″ was lying over it. The bladder was closed without drainage, and a retention catheter inserted.

His progress has been very satisfactory since th operation; there has been no leakage of urine throug the incision. The patient was able to void after th third day when the catheter was removed. There ha been no residual urine since the operation, his temperature is normal, and he has had no vomiting. H was out of bed on the fifth day.

The conclusions and interesting factors about thi case are: the unusual size of the stones, one ston being almost completely encysted back of the prostate, the pronounced symptoms of gastrointestinal disturbance, the loss of blood and loss of weight, an the supposition by friends and a physician that a cancerous growth existed. The decision not to remov the prostate, although considerably enlarged, wa reached as the residual urine and size of the prostat was thought probably due to the presence of the stone The rapidity of progress after the operation, the lac of residual urine and the disappearance of all symptoms a few days after the operation were gratifyin

---

Dr. Francis F. Callahan (Pokegama) read hi thesis, entitled "Collapse Therapy in Pulmonary Tuberculosis," and showed slides of X-ray films of a numbe of cases.

DISCUSSIONS

Dr. D. G. Gardiner (St. Paul) (by invitation): have enjoyed Dr. Callahan's paper very much. Mos of the phrenic nerve resections you have seen on th screen have been rather recent—in the last 3 or years. Some of them speak for themselves. Lookin at the slides in these cases is like looking at autopsie —one sees some of his good and bad results.

One thing Dr. Callahan mentioned in his paper bu I do not think stressed sufficiently is the meticulou postoperative care necessary over such a long perio of time. This consists in the application of very tig adhesive strapping to the whole affected side and renewing them, each time tighter, every few days. Thi can be augmented by sand or shot bags over the lesio to aid in compression. The good results one gets fo lowing thoracoplasty are attributable to the clinicia who takes charge of the patient after operation. I als speak for Dr. Daugherty in this connection in his wor at Ancker Hospital and Pokegama Sanatorium. A fe years ago I remember seeing a patient who was operated for lung abscess. A classical two-stage thoracoplasty had been done by a general surgeon who wa not familiar with the necessity for such postoperativ care and except for the scar on his back one coul hardly tell which side had been operated. His X-ra picture showed complete regeneration of ribs follow ing thoracoplasty with full return of symptoms. Th lesson to be drawn from these is that convalescenc following thoracoplasty takes a period of months an tedious care.

I think many of the good results that any one ge after phrenic nerve evulsion should be credited to th clinician or the man in the sanatorium who gives th same care postoperatively to the patient that he do

-operatively. The selection of these cases is a very
icult problem and the clinician sometimes picks
es which even with his very best judgment are not
able for thoracoplasty but could tolerate a phren-
tomy and a long period of observation thereafter
ause phrenicectomy is in itself a simple operation
h very little possibility of doing harm attached to
I have had about 150 phrenic nerve evulsions and
e not seen any complications from them. Many
es they are only a test as to whether or not the
ient can stand thoracoplasty, and in many instances
y are sufficient to alleviate the symptoms, which
lly amounts to a cure.

r. Callahan mentioned the indications for thoracic
apse and for phrenic nerve evulsion, but of course
ideal type of phrenic nerve evulsion is the case
h the basic lesion. Unfortunately tuberculosis does
always strike the base; it usually is an upper lobe
on. In our cases at Ancker Hospital there have
n 6 cases of upper lobe lesion which have closed
owing phrenicectomy but as yet we have not seen
uitably proven case of basal tuberculosis.

think Dr. Callahan's review of the literature of
subject has been quite complete and think it speaks
l for his conservative management and attention
has paid to the cases coming under his care and
owing the cases for a long time postoperatively,
ch I think is an important point.

R. H. Longstreet Taylor (St. Paul): It seems
dly fair to go away from a subject as recent as
without going back to see how it has gradually
lved from the dark days of the 70's. In my own
erience I can recall when we had no tubercle bacilli
ook for, or at least we did not know we had them;
had no tuberculin to test with, no X-ray, and no
apse therapy. It is not so far back now since the
lsion of the phrenic nerve and thoracoplasty have
e into use. In the olden times when families were
ticular about their insurance standing, the death
ificates were nearly always "chronic bronchitis."
t lasted until the examinations for tubercle bacilli
e in.

rudeau, in his Life, says that he picked Baldwin out
a scientist because he came to him saying that he
tuberculosis of the lungs. Trudeau asked him how
knew he had tuberculosis, and Baldwin replied,
cause I have demonstrated tubercle bacilli in my
tum." Trudeau took him in and put him at the
d of the research department at Saranac Lake, where
still is. Few men would be called scientists today
ause they knew how to stain tubercle bacilli.

t is certainly very interesting to think of the
nges which the last 50 years have brought in the
tment of tuberculosis and the increased possibilities
recovery that are offered to the patient by the ar-
mentarium we have at the present time with which
handle this very serious disease.

R. H. E. Michelson (Minneapolis) read a paper on
udies on the Lymphatic Glands in Early Syphilis."
les of pathological studies were shown.

ABSTRACT

Dr. Michelson reported on his studies over the past two years on the superficial lymphatics in early syphilis; and his conclusions were as follows:

1. One hundred and forty-five lymph nodes excised from patients with untreated syphilis were examined.
2. In approximately 27 per cent of the specimens, tuberculoid structure was present.
3. The test with tuberculin, performed on 14 patients whose glands showed tuberculoid structure, was positive seven times.
4. The luotest was negative when performed on 9 patients whose glands showed tuberculoid structure.
5. Tuberculoid reactions found in the lymphatics in early syphilis are variable in type, and apparently the state of allergy is not the same as when this reaction is found in the skin.
6. True gammas of the lymph nodes differ from the tuberculoid structure found in the nodes in early syphilis.

DISCUSSION

Dr. J. F. Noble (St. Paul) (by invitation): Those of us who are interested in general pathology are particularly grateful to Dr. Michelson for this and similar histologic studies which he has carried out on dermatologic problems. The general pathologist is lost when it comes to the diagnosis of skin diseases. These lesions, to him, are simple acute or chronic inflammatory processes and it requires special study such as Dr. Michelson has given the subject to be able to recognize the finer diagnostic changes.

The microscopic pictures which Dr. Michelson has shown this evening, are, as far as I can determine, indistinguishable from tuberculosis. Tuberculosis of the lymph nodes shows two types of histologic reaction, the caseating lesion and the proliferative tuberculous lymphadenitis. The gummatous lesions are not likely to be mistaken for tuberculosis.

With reference to the question of allergy, I think Dr. Michelson is correct in concluding that this type of inflammatory reaction is not characteristic of the allergic state. Rich, Clawson and others have definitely shown that allergic inflammation may vary in degree from a slight proliferative reaction to abscess formation.

Dr. Michelson's work also brings up the question of the function of the lymph nodes in this type of infection. His work seems to show that the lymph nodes attempt to localize the infection but clinical and experimental data point to the fact that the spirochete promptly passes lymph node filter and the infection becomes generalized.

Dr. C. B. Wright (Minneapolis): For my own information, I would like to ask Dr. Michelson how he excludes the possibility of tuberculosis in these cases. Tuberculosis is a very common disease and many of these cases may have tuberculosis in addition. How do you prove that this is not a tuberculous lesion?

Dr. E. M. Hammes (St. Paul): I would like to ask Dr. Michelson if these 28 per cent of cases of early syphilis showing this reaction are more or less prone to develop central nervous syphilis later on in life.

Dr. Michelson (in closing) said he would like to emphasize what Dr. Noble said about the action of the lymphatic glands. It was previously thought that these nodes acted as barriers, but the work of many investigators in experimental syphilis had shown that the adenitis was part of the general reaction to the infection and that spirochetes could be found in the blood stream and even in the spinal fluid before there was any demonstrable lymphadenitis.

In answer to Dr. Wright's question, the cases had all been passed upon by Dr. S. E. Sweitzer, and there was no question that clinical syphilis was present. Another strong point against tuberculosis was that when a patient had a bilateral adenitis which was clinically syphilis and a gland was removed from one side, and under anti-syphilitic treatment the adenitis subsided, it was a fair presumption that tuberculosis was not present, because colliquative tuberculosis occurring in lymphatic tissue is notoriously slow to respond to any treatment, and heals only after complete elimination of the focus. Stains for tubercle bacilli had been made and were always negative. Dr. Bell also emphasized the point that liquefaction had not been found in any of these specimens.

The question that Dr. Hammes asked is the very one we have put to ourselves: What significance has this finding in a prognostic way? I am sorry to say we are unable to answer.

R. T. LaVake, M.D., *Secretary.*

LIMITATION OF THE MANUFACTURE OF NARCOTIC DRUGS

In accordance with the provisions of the Hague convention of 1912, Congress made laws for controlling and regulating the production of and the traffic in the drugs mentioned by the convention. Now domestic production and traffic in these dangerous drugs is limited by federal law. The importation of opium and coca leaves into the United States is restricted. The enforcement of the laws have, however, not prevented the importation of drugs for illicit uses. Introduction of narcotic drugs by smugglers cannot be prevented until other countries control the manufacture and export of narcotic drugs adequately. To this end our government initiated the movement which resulted in the calling of the International Opium Commission at Shanghai in 1909 and since then has continued in its efforts along these lines. The manufacture of narcotic drugs must be limited to approximate medicinal and scientific needs. Physicians must aid in the determination of such needs by limiting their own prescribing to indispensable uses. The pitiful character of the drug addict and the association of drug addiction with crime and other menaces to the public welfare demand all the help that physicians can give in solving this problem. (Jour. A. M. A., May 9, 1931, p. 1623.)

PROCEEDINGS OF THE MINN APOLIS CLINICAL CLUB

Meeting of May 14, 1931

The regular monthly meeting of the Minneapo
Clinical Club was held on Thursday evening, May
1931, in the Lounge of the Medical Arts Buildi
After dinner, the meeting was called to order by
President, Dr. F. H. K. Schaaf, at 7 p. m.

After a short business meeting in which amendme
to the Constitution and By-Laws were voted upon,
following scientific program was given.

Dr. R. T. LaVake read a paper entitled "Preëclamp
Toxemia of Pregnancy":

The aim of this paper is to stress a clinical obser
tion that I believe to be of the greatest practical i
portance, namely, the increased likelihood of the acc
sion of preëclamptic toxemia of pregnancy coincid
with or as a sequel to any type of infection, focal
general.

This observation led me to espouse the infect
theory of eclampsia in an article appearing in the Oc
ber 15, 1916, number of the Northwestern Jour
Lancet. A continued study of this problem during
past fifteen years had convinced me that this obser
tion is of the greatest practical importance from
standpoints of prophylaxis and preparedness. It dire
the clearing up of all focal infection in teeth, tons
sinuses, etc., and when infection—focal or genera
cannot be avoided, it directs increased care in look
for the earliest signs of preëclamptic toxemia. Althou
no one has been able to prove the infection theory, i
my belief that it will eventually be proved.

I feel that this paper is timely because I have
finished a review of obstetrical literature to date on
subject and have visited many outstanding clinics
find that it is generally held that the infection the
has been discarded as untenable from the results
investigation; and the clinical observation of the
quency of the accession of this toxemia upon any t
of infection is not made and stressed.

As an example of the practical importance of giv
this theory careful attention, let me cite one case am
many. A woman normal in every way, whom I had
livered normally twice before, contracted in her seve
month of pregnancy what she designated as a c
It was apparently so slight an infection that it did
confine her to bed though it lasted a week and
was quiet during that time according to her physic
and herself. Three weeks later her urine was a
lutely normal and her blood pressure was 120/60
she said she felt in perfect condition. However,
history of infection put me on my guard and a w
later being called up by her and questioned as to
best thing to take for a slight headache, I insisted
I go out to see her. She demurred at this, saying
she and her husband were all dressed to go out to
ner and that my seeing her was unnecessary. I insis
however, and found her systolic pressure 240. We w
to the hospital instead of to the dinner. Labor was

d by bags and the case terminated well. She never a convulsion but I felt that early and prompt at- on should be given some credit in the result.

t us use this case as an example for theoretic oning and permit me to describe how I believe in- on brings about this condition. It must bring it it through its action upon the fetus or placenta and my belief from observation that it does so by pro- ng alterations in the placenta, generally grossly alized by infarctions, and that either autolysis of e infarctions causes the toxin, as brought out by ng of Edinburgh in 1914, or the alterations in the enta permit of products being absorbed from the s that produce the lesions. The frequent pro- nced improvement following intrauterine death of fetus lends some weight to the latter theory.

st because we do not know absolutely the cause of toxemia, do not let us ignore the possible signif- ce of the sequence of infection and toxemia. ecially, whether right or wrong, it can only act to ease our efficiency.

here are several stock arguments against the infec- theory that I would like to mention because they ediately deter many men from thinking further it it. One is: Nearly everyone during pregnancy have either some focal infection or some general ction, however slight. Why do not more women preëclamptic toxemia? One may say the same rheumatic fever. Has any one yet solved the prob- of why one will have joint involvement with a h or tonsil infection, and another not? A parallel ation may apply to alteration in the placenta.

nother argument is: The large majority of pla- æ show some infarction and yet only a small per- age develop toxemia. True, but one must consider the accession of toxemia depends upon the inability he excretory organs to take care of the toxin, what- it may be; and again, from my knowledge of the nation of the placenta, where every cell likely ob- s one-half of its proteins from the male side, no placentæ would be alike in their toxicity to that icular mother.

nother argument is that there is no evidence that rcts are even the results of infection. They may ust an evidence of an aging organ or the abnormal ation in a rapidly growing organ. I can merely that practically every placenta from patients mis- ying or having premature labor in the great Flu emic were filled with infarcts. This phenomenon rs in miscarriages during every general infection. eful gross observation of placentæ in general infec- directs attention to the likelihood of placental ation due to the infection. Otherwise why should e placentæ show such tremendous infarction com- d with placentæ from normal cases.

reëclamptic toxemias also show a greater average rction. Some of them, when not showing infarc- , show local areas of color change that suggest a y alteration. Whether or not these areas are the nnings of infarction, I am not prepared to state.

onclusion.—No theory of preëclamptic toxemia is of ter practical value than the infection theory. Keep it in mind for practical as well as experimental purposes until it can be absolutely disproved.

DISCUSSION

Dr. F. H. K. Schaaf: Of course, the relation of focal infection to sytemic disease is always going to be very much debated, and, while we may suspect it as a factor from a clinical standpoint, it will be difficult to prove our views from a pathological standpoint. This is true not only in preëclamptic toxemia but also in myocardial degeneration. Pathologists at the present time do not admit that focal infection can be a factor but at the same time we see many cases of myocardial degeneration where it is utterly impossible to find any other etiology. I fear there always will be arguments pro and con.

Dr. H. B. Dornblaser: I think this paper is very timely. I enjoyed it very much. On looking through my own records of preëclamptic toxemia, with the idea in mind of an infection as the cause, while not all of the cases had a note to the effect that the patient was suffering from infection, my recollection of some of them was that there had been some focus of infection present—a sinus, bad tooth, or something of the sort. When one looks at these cases with the idea of infection in mind, he often finds it is there although it did not seem to be a very big factor at the time. I think it is something obstetricians will have to watch carefully, and the essayist is to be congratulated on his prompt action in seeing the patient who complained of severe headache.

Dr. F. W. Wittich read a paper on "Indications for Therapeutic Abortion in Tuberculosis."

ABSTRACT

The influence of pregnancy on the tuberculous woman was noted in the early centuries. Statistics of various writers are noted showing that pregnancy is one of the leading factors in lighting up an inactive process—that in 30 to 40 per cent of married women pregnancy was responsible for lighting up an inactive process and that the disease proved fatal in about 30 per cent. The death rate is higher, the closer the period between the disease and the pregnancy and the more advanced the disease. Tuberculous women having sanatorium training do not become pregnant as often as normal women. Postpartum hemorrhages occurred in a very large proportion of the tuberculous women.

No bad effects were noted after 80 artificial abortions noted among the discharged Trudeau Sanatorium cases reported by Matthews and Bryant, and a few onsets and recurrences occurred after some of the 101 spontaneous abortions noted by them. Of their series 71 per cent of those who bore living children nursed their babies in spite of the general teaching against nursing by tuberculous women.

The writer studied a group of 515 definitely active cases of tuberculosis among women of all ages and stages of the disease from his private files between the years 1917 and 1931. One hundred seventy-eight gave histories of having one child or more, of which 95 are living and 83 are dead. Of 337 who gave a history of never having been pregnant, 169 are living and 168 are dead. Very little difference was noted between the number of deaths between the maternal and non-maternal group, although this is influenced by the fact that among this series were a comparatively large number of young women between the ages of 15 and 25 years who were never pregnant and who had rather an acute advanced stage at the first examination, where the disease was advanced beyond the stage where collapse therapy could be done, whereas the older maternal group presented more of the fibroid type more limited in extent and where artificial pneumothorax played an important factor in prolonging life. There were 23 induced abortions in the entire series, five of whom are dead, 16 living, and two untraced.

Abortions should be decided upon before the third month, or as early as possible, and never later than the fifth month. The active early cases are the most suitable and the moderately advanced less so. In cases complicated by hyperemesis or laryngeal tuberculosis, abortion should be done in the early months. Artificial abortion should never be done on a tuberculous suspect and collapse therapy in some form should be considered in all cases. The acuteness and rapidity of spread of the disease should be considered, as abortion influences cases with a rapid recent spread very little. Artificial abortion should not be done in any case unless the patient can have excellent care and undergo the strictest and accepted anti-tuberculosis measures, preferably in a sanatorium.

As the indications for such a procedure become more complicated where the symptoms, physical signs, X-ray, and knowledge of collapse therapy play an important role, it should be required of every tuberculous pregnant woman to have the benefit of the roentgenologist and the internist versed in the special therapeutics of tuberculosis, as well as the obstetrician. A thorough chest examination and, if possible, X-rays should be taken of every prospective mother as a routine prenatal procedure.

DISCUSSION

Dr. R. T. LaVake: This is a very timely paper. It has always seemed to me, in this question of tuberculosis and pregnancy, that the whole thing from beginning to end hinges on the questions: the perfection of sanatorium or sanatorium-like treatment, how much you can protect the patient from work at the time of labor, and how well you can keep the affected lung immobilized. I haven't had experience with phrenicotomy, but that seems to offer the best solution to this problem. I have never seen a case where pregnancy seemed to interfere with the well-being of the woman; in fact, it has always seemed to me she has felt better from the pregnancy, after the first three months, than she had ever felt before. The circulation of the extremities is bettered as a rule. I believe that pregnancy improves the general well-being of a woman. The same applies to the tuberculous woman but the danger lies after delivery when you change the position of the diaphragm, which is practically in the position that it is after phrenicotomy; it is suddenly allowed to come down and that just shoots the tubercle bacilli through the lungs. The reason, in my opinion, why abortion should be p formed before three months have elapsed is beca there has been no disturbance of the diaphragm and muscles have been brought into play. These patients loose a little blood, but often this is not in exce Personally, I believe that a woman who has h active tuberculosis within two years, if seen wit the first three months, should be advised to have t pregnancy terminated. Of course the religious fact and her own desires must be taken into considerati If she goes to delivery I think she should have phrenicotomy or a pneumothorax, and one can do cesarean under local if necessary to prevent all effo The vital capacity of the lungs is the same at the ti of delivery but the lungs are flattened from abo downward. As soon as the pregnancy is ended, the d phragm falls and the lungs resume their normal sha I think that a phrenicotomy or a pneumothorax is adv able. I have not used them, but have always advis putting a pillow over the uterus after delivery, th attempting to hold the diaphragm up. I believe that we could absolutely prohibit the change in the d phragm or the mechanics of the lung, the woman shou have no trouble at all. She should, however, be at sanatorium and under the best care.

Dr. H. B. Dornblaser: I was very much interest a week or so ago in attending a meeting at Glen La Sanatorium in which Dr. Jennings reported their s tistics for the last ten years on 35 cases of pregnan in the tuberculous patient. At first they picked th very sparingly, but have come to the conclusion t they can carry nearly any with tuberculosis through pregnancy. His statistics in the early cases were abo the same, whether the case was aborted or allowed go to term. They felt they had not gained much aborting them early. The majority of the women t have taken through their pregnancies, and their tub culosis was in no way advanced. They do sugg however, that the woman should be given as easy labor as possible, and should have the best possible c for the tuberculous patient afterwards, *i.e.,* should be bed for at least three months and go on a cure, and a that the baby should not nurse. I have a patient n who has an active tuberculosis and insists on goi through her pregnancy. When I first saw her I thoug it was suicidal to do it. She had been a patient Glen Lake. She says that as soon as the delivery over she will take a cure either at home or go to G Lake.

Dr. F. H. K. Schaaf: It seems to me that we h to consider each case individually and make a decis accordingly. Firm and fixed rules cannot be formula for any therapeutic procedure.

Dr. LaVake: In the case Dr. Dornblaser just m tioned, if I may offer a suggestion, when that wom delivers I certainly think she should have a pneum thorax or phrenicotomy or she may not get to the sa torium after delivery. When that diaphragm co down it is too late, but with either of these procedu there is less chance of that happening. I have s cases, apparently well at an easy delivery, cough u teacupful of pus filled with tubercle bacilli a few d er and die within a few weeks. I don't think that ould occur now with the means at hand for lung im- obilization.

Dr. J. M. Hayes: I would like to ask if Dr. Dorn- aser's case is bilateral tuberculosis?

Dr. Dornblaser: Yes.

Dr. E. S. Platou: Are all cases of pulmonary tuber- losis with pregnancy suitable for immobilization and ien is the optimum time for such immobilization?

Dr. R. C. Webb: Are there any objections to renicotomy, or would it be preferable to crush the renic nerve and let it recover at a later date?

Dr. Wittich: I think, but am not positive, that Dr. nsella just crushed the nerve in some of his earlier ses, but I do not see why it should not be pulled out get as much fixation of the diaphragm as possible.

Dr. Webb: Then you don't do phrenicotomy as a ophylactic measure; but should it have been done be- re?

Dr. Wittich: It should have been done previously rhaps if the disease had been detected before the egnancy where this procedure is indicated, but the egnancy may be the only indication for phrenic eresis. It is rather difficult to get the patient's con- nt sometimes, and then again many physicians are not miliar enough with the procedure or realize its im- rtance in these cases. Personally, I prefer to do eumothorax if possible, taking the side having the ost disease, when the lung can be allowed to re-expand results are not obtained, or there is increased activity the opposite lung. Phrenic exeresis is a permanent ing and this may not always be desirable.

Dr. E. T. Evans: On the other hand you have had period of four months in which it was doing some od.

Dr. Webb: If phrenicotomy is better why would you en consider pneumothorax unless you had some ob- ction to phrenicotomy?

Dr. Wittich: Pneumothorax has always seemed a mple procedure to me. Besides a phrenicotomy pro- ices far from the satisfactory collapse that a pneumo- iorax will give; the former, however, is certainly a ost valuable procedure when indicated.

Dr. LaVake: It would seem to me that phreni- tomy would be better, then you could do a cesarean, id I do not think it would hurt the woman at all.

Dr. Webb: I think some years ago Dr. Wittich read paper on the relation of vital capacity to post-opera- ve risk. Can a patient hold the breath as long after irenicotomy as before?

Dr. Wittich: No, but the vital capacity gradually proaches its former level.

Dr. Webb: Then you would prefer pneumothorax ecause the lung comes back afterwards, while with irenicotomy you have lost the action of the dia- iragm?

Dr. LaVake: One thing which has not been brought it and which seems to be a very wise thing, and that that every patient who has had tuberculosis within vo years the patient should be given advice not to become pregnant until the lesion is entirely gone. I do not believe they get such advice.

Dr. Platou: It is true that some women never suspect they have had tuberculosis and after having a baby break down with rapidly progressive tuberculosis.

Dr. LaVake: I think Dr. Wittich mentioned there were about 33 per cent.

Dr. Platou: Don't you think that is a good argument for a very careful study of the patient who becomes pregnant, with at least one routine chest plate during her course?

Dr. LaVake: I am of the opinion that that diaphragm must never move once. One case was very interesting to me. This woman had aborted twice by herself. I think every woman who has aborted should be gone over by an internist to find out if she has a focal infection. The third time she did not abort. She was a patient of Dr. Bell and we went over her very carefully and then advised abortion. She refused, went out to Colorado, and died three weeks after delivery.

Dr. F. W. Wittich reported the following case and showed the two complete specimens of diphyllobothrium latum or fish tapeworm. These specimens were passed by a native born Jewish woman 65 years of age after vigorous anthelmintic treatment. She had had a moderate diabetes mellitus for about five years and four years ago entered the hospital, where she underwent treatment for worms, but the physician failed to get the heads. There were little or no sympatoms. She presented a moderate secondary anemia. Attention is here called to Dr. Moses Barron's excellent paper in the Journal of the American Medical Association of May 11, 1929, reporting 19 cases among native born Americans, four of whom were his own cases. He calls attention to the fact that the majority are Jewish, and mostly women, who are accustomed to tasting from time to time, for proper seasoning, the raw minced fish while preparing the commonly used Jewish dish of "gefüllte fish." The woman gave this history. She had frequently tasted the raw minced fish in the preparation of this fish.

The one specimen shown is 18 feet long and the other seven feet long. These worms are often eight meters in length. Attention is called to the lateral slit in the head and to the split tails. It is noted that, besides man, the dog, cat and fox have been found to be infested; that there are two intermediary hosts: the first larval stage developing in infested crustaceans from ova discharged in the stools, and the second larval stage in the body of the fish from ingesting infected cyclops, or from eating infected young fish.

Magath and others have shown that some of the northern lakes of Minnesota are heavily infested, especially the pike and pickerel. The larval worms are also seen in carp.

The treatment in this case was as follows: For three days before entering the hospital, the patient ate lightly of milk, milk toast, cereals, broth and coffee. On each of these days she was given a tablespoonful of a solution of Epsom salts containing spirits of chloroform 15 c.c. and 60 grams of magnesium sulphate to 200 c.c.

of water, three times daily before meals. The night before entering the hospital a double dose of the salts mixture was given and a soap and water cleansing enema, and the patient took no food and but little liquid. The patient entered the hospital before 9 o'clock the next morning, when four 0.5 gm. capsules of oleoresin aspidium was given. This dose was repeated at 10 o'clock. The capsules were uncapped before giving. At 12 o'clock 3 tablespoonfuls of the salts mixture was given to prevent absorption of the male fern.

The patient remained in bed the entire day, taking only some black coffee and a little bouillon during the morning. In the afternoon the patient was given a light diet. All specimens were carefully searched by straining through gauze, and a final high cleansing enema was given that night.

Secretary.

"DISEASED" BUILDINGS

Several articles have appeared recently in medical journals calling attention to inaccuracies often noted in scientific terminology, or nomenclature, not only in secular periodicals and newspapers but in technical bulletins as well.

A well known tuberculosis laboratory has issued a circular announcing that a "Tubercular Building" for children was to be erected. This is a misnomer commonly used even among medical workers. Those who know have repeatedly pointed out that a diseased organ may be "tubercular," but the patient is "tuberculous." It is to be hoped that the building in question will not suffer from this type of organic condition, at any rate not for some years to come.

In the field of mental hygiene it has been necessary to explain to the uninitiated the difference between "mental defect" and "mental disease." But we too have been careless with our psychiatric vocabulary. Why the "Psychopathic Hospital"? There may be "psychopathic social workers" but state hospitals and mental hygiene clinics try as far as possible to employ safe and sane "psychiatric" social workers. Facetiously, and for the sake of brevity, professional workers have referred to students of mental deficiency as the "feebleminded group."

"Insane" is a good old fashioned word, try as we might to discard it as a medical term, but why announce, as does a current bulletin, that the foundations have been completed for two "disturbed buildings" and two "epileptic buildings" for the blank "insane hospital"? Have you ever seen a "nervous hospital"? But even the purist is stumped at "mental institutions," the phrase has come into such general use. The technologists have given us the televox, the electric man and the robot, but it takes a psychiatrist to endow a hospital for the insane with mind.—*National Committee for Mental Hygiene.*

PROGRESS

Abstracts to be submitted to Section Supervisors.

Members are urged to abstract valuable articles whi they run across in their reading and send the abstra to the physicians in charge of the respective sections. order to avoid duplication it would be well to commu cate with one of the section supervisors before t article is abstracted.

EYE, EAR, NOSE AND THROAT

CHOLESTEATOMA: Alexander Retjo (Arcl Otolaryng., May, 1931, Vol. 13, p. 709). Microscop examination of material from the suspected case an the roentgen ray do not give useful information in large percentage of cases. Virchow brought out th fact that cholesterol is not peculiar to the cholesteatom masses, since it is found in many other parts of th body. The cholesterol content of these epithelial masse is exceedingly inconstant and varied (Lucæ). Salkow ski's investigations showed that although there is alway cholesterol in the cholesteatoma, it may be in an amo phous state instead of in the crystalline form. Crysta line cholesterol is an alcohol of high valence; th amorphous cholesterol is its ester. Lautenschlager dem onstrated that the agent that destroys the bone is th chemical effect of cholesterol and not the mechanical pressure of the tumor as was formerly believed.

According to Salkowski's estimate, there is 10.6 per cent cholesterol that is cholesterol ester in the normal epidermis and 18 to 23 per cent in the cholesteatoma of the middle ear. The content of cholesterol found in the normal epidermis may be doubled in pathological conditions. As to the causes and conditions that produce this variation, it is known that epidermis normally grows in dry surroundings, that is, in contact with air, but becomes degenerated and changes to matrix in the presence of moisture when air is absent and in a dark place. The author, observing the deleterious effect of aqueous solutions on the effort of nature to epidermatize a deep aural space, sought a substance capable of drying and also of dissolving cholesteatomatous masses. He is now using carbon tetrachloride for this purpose.

For the chemical demonstration of cholesteatoma, the author has applied Bloor's method to the examination of the barbon tetrachloride extract and devised a colorimeter for index of the quantity of cholesteatomatous material. The author hopes that others will apply his method so that larger series will be reported.

Lawrence R. Boies.

SINUSITIS IN CHILDREN: Henry A. Riesman. (Archiv. Ped., May, 1931, Vol. XLVIII, Page 283). In climates similar to that of New York City, sinusitis is a disease fast becoming a problem of paramount importance, because of its increasing prevalence, the difficulties in diagnosis, the resistance of sinusitis to treatment, and its complications and sequelæ. Marriot is quoted, who stated that more than one-half of the children in hospital wards are under treatment for some form of paranasal sinus infection regardless of the diagnosis on admission.

Two diagnostic signs additional to those commonly sought for are emphasized: the enlargement of retropharyngeal glands apparent directly behind the posterior tonsillar pillars, and the elicitation of submaxillary tenderness at the midline of the body of the mandible.

The author has found, in a comparatively large number of cases, secondary pulmonary infection resulting from a primary sinusitis to involve the central lung field, and to present a picture so similar as to be at times very confusing with that of juvenile tuberculosis.

The relationship between avitaminosis and accessory nasal sinus infection must be an indirect one, probably due to the lowered resistance of the cells of the upper air passages to infection. If this were not so, then our diet treatment for sinusitis, rich in all the vitamins, would be either specific or at least more successful, which is not the case. There is no doubt, however, that a diet rich in fat is beneficial.

The difficulty of X-raying children and the short duration of the infection may be factors in obtaining negative findings in the presence of positive clinical evidence corroborated by nose and throat consultation.

The author believes, despite contradictory opinions regarding the use of vaccines, that if the vaccine is autogenous and properly prepared and given, a greater resistance to nose and throat infections is developed. Though it may be temporary, the treatment is justified. Details of the author's method of preparation and administration of the vaccine are given. He recommends a diet high in fat and protein and comparatively low in carbohydrate—essentially the diet used in tuberculosis. Alpine therapy is considered to be of minor value. Rest and the prevention of over-fatigue are important.

Lawrence R. Boies.

THE PROGNOSTIC VALUE OF EXAMINATION OF THE BLOOD IN OTOLOGY. Arthur Weiss (Arch. Otolaryng., May, 1931, Vol. 13, Page 647). Weiss reports a study of the leukocytes in acute otologic infections, evaluating the usefulness of interpreting the differential study according to the method of Schilling. To quote the author: "The physician of yesterday, depending on the number of leukocytes and the percentage of polymorphonuclears for his information in cases of severe infections, often found himself unable to explain apparently contradictory relationships. With the appearance of the work of Arneth and Schilling, this apparently false relationship was clarified and explained. Today, while the actual number of leukocytes is of but casual importance, the number of immature neutrophils or staff cells has achieved the center of the stage."

The author has found that for matters of diagnosis, inconsistencies exist in the reactions called forth by the various types of disease, and therefore the immature count is not of particular use as an aid to diagnosis. For instance, a case, of acute otitis media purulenta, which usually precedes the infection of the mastoid, may give a more active response than the latter. This, Weiss explains by suggesting that infection of the middle ear and sinus often result in a severe systemic involvement, whereas infection of the mastoid, usually only a localizing or pointing of the otitic inflammation, causes few if any symptoms and either gives normal figures in examination of the blood or shows evidence of slight stimulation.

His conclusions emphasize the following:

1. A rise in the percentage of staff cells indicates the presence of some postoperative complication, though the complication may not be in the postoperative area. 2. The leukocyte and staff counts are often much higher in acute otitis media purulenta than in acute mastoiditis. 3. All cases of mastoiditis with venous complications show marked changes in the blood picture. 4. The blood count when used in series is of inestimable importance in prognosis.

(Comment: In a paper on the same subject in the February Archives of Otolaryngology, I brought out the fact that the immature count reflects the intensity of the toxemia. Whether the toxemia results from otitis media alone, or from mastoiditis or a complication, there are factors both anatomical and bacteriological in the course of the suppurative process which influence the degree of toxemia. The immature count is an aid to diagnosis to the extent of information as to the balance between invasion and resistance, in some instances of which the usual manifestations are not prominent.)

TUBERCULOSIS ABSTRACTS*

The Twenty-seventh Annual Meeeting of the National Tuberculosis Association, held at Syracuse, New York, May 11-14, 1931, was attended by 1,010 registrants. Papers and discussions dealing with the pathological, clinical, social, and administrative aspects of tuberculosis furnished a well balanced program. While most of the papers were of interest primarily to specialist groups, all contributed to our general knowledge of tuberculosis. All papers, either in their entirety or as comprehensive abstracts, will be published a few months hence in "Transactions of the National Tuberculosis Association." A few high lights of general interest are here presented.

TUBERCULOSIS WORKERS REPORT PROGRESS AT ANNUAL MEETING

The opening session celebrated the twenty-fifth anniversary of the Christmas seal, the device which made possible the financing of the tuberculosis movement in the United States. Miss Emily P. Bissell, who introduced the seal in this country, was the guest of honor.

Dr. Livingston Farrand, president of Cornell University, who served as executive secretary of the National Tuberculosis Association from 1905 to 1914, described how the Christmas seal sale grew from $3,000 in 1910 to $5,350,000 in 1930. The total receipts from this method of fund raising in the United States have aggregated $58,640,000. This money has been used largely for the promotion of official measures designed to combat tuberculosis, and by this means there have been secured from the public purse sums that aggregate at the present time close to $500,000,000. "Christmas seals invested in community organization have resulted in dividends of incalculable benefit."

Emily P. Bissell recounted the origin of the Christmas seal. She was interested in 1907 in raising a few hundred dollars to provide a small sanatorium of 8 beds for consumptives in Wilmington, Delaware. Having read Jacob Riis' description of the Danish Christmas seal in "The Outlook," she decided to adopt the method. The first seal issued aroused scant interest until "The Philadelphia North American" gave it publicity and proved the possibilities of raising money through the sale of penny stickers. The seal was not a sudden inspiration or a detached idea. As a social worker, Miss Bissell had learned that fairly large subscriptions may be obtained for a worthy project from a few individuals if it is explained to them. But the real public, the people who can afford to give from ten cents to one dollar, are difficult to reach. The Christmas seal makes it possible for all to participate and also enlists widespread individual interest in the problem of tuberculosis.

MEDICAL RESEARCH

Dr. Florence R. Sabin outlined the program of the Committee on Medical Research under the chairmanship of Dr. William Charles White. Under the plan, various universities and laboratories throughout the country coöperate in the solution of carefully outlined problems. All the groups engaged in the work meet frequently and discuss their progress.

One of the projects is that of subjecting strains of acid-fast bacilli, of which the tubercle bacillus is one, to chemical analysis. The essential foundation for such a survey is a synthetic culture medium of known and constant composition free from any protein, complex carbohydrates, and lipoids. The various products of the medium, as well as the chemical fractions of the tubercle bacillus, are submitted to biological tests in order to determine the specific physiological reaction of each fraction or pure substance. For example, saturated fatty acids derived from the tubercle bacillus reproduce typical tubercles in animals. Both proteins and carbohydrates derived from the tubercle bacillus reproduce the toxic symptoms characteristic of the disease. After each new fraction of the tubercle bacillus is isolated, it is tested in the biological laboratory, the end in view being to formulate a complete catalogue of the component parts and their physiological reactions.

Other studies include an investigation into the physiology, particularly the respiration rate, of living tubercle bacilli. One worker has devised a means of isolating a single bacillus and watching its entire life cycle under the microscope. Another group is attempting to standardize the reading of X-ray plates and the construction of X-ray equipment.

NEW DISCOVERIES ANNOUNCED

At the meeting of the American Sanatorium Association, one of the affiliated groups, several important research developments were announced. Dr. E. Fenger of Glen Lake Sanatorium, Minnesota, speaking for the group who participated with him, reported on a new tuberculin known as MA-100. This is a protein common to all acid-fast bacilli. The combined results of several investigators justified the opinion that the new tuberculin possesses four distinct advantages: (1) it is free from all substances that might render the positive reaction uncertain; (2) it can always be produced at the same iso-electric point in precipitation; (3) it contains nothing except what is manufactured by the germ of tuberculosis itself; (4) it can be diluted in quantity accurately to enable every physician to know exactly how much of the active element he is using.

Professor Charles Weyl of the University of Pennsylvania, technical adviser of a group headed by Dr. F. Maurice McPhedran who are endeavoring to standardize X-ray equipment, announced a method of making X-ray pictures of the chest so synchronized as to take several short exposures between heart beats. The resulting composite negative produces a clear picture free from blurring caused by the heart's action. Professor Weyl compared the mechanism of the apparatus with that used in a combat airplane, whereby machine gun bullets may be shot between the whirring propeller blades. The device marks a step in advance towards standardizing X-ray pictres.

---

*Reprinted from Tuberculosis Abstracts, a review for physicians, issued monthly by the National Tuberculosis Association. August, 1931, Vol. IV, No. 8.

Another advance in the work with the X-ray was made public at the meeting by the same group, who have been attempting for several years to eliminate variations in the results obtained with different X-ray machines. Differences in lighting and mechanical action of apparatuses heretofore have made the accurate reading of negatives depend upon due allowances for peculiarities known to exist in the operation of the individual machine. For example, pictures made in one city with a certain apparatus would be found, if the patient moved to another city, to be of little use in diagnosing progress of tuberculosis because the second physician would not be conversant with the variables characteristic of the first machine.

By means of an instrument called a "comparator densitometer," designed and constructed by the group making the report, a standard is established which the operator can use to know in advance of taking the X-ray that a certain established density in the picture will be obtained. This enables physicians in different parts of the country to work with X-rays upon a uniform basis, as well as reducing the variations that have stood in the way of accurate judgment.

In addition to these developments, it was announced at the meeting that a fixed resistor has been designed which will test the supply of electrical current; also a peak voltmeter for vacuum tubes, and a standard testing apparatus which will help hospitals, sanatoria, and laboratories to choose the X-ray machine best suited to their needs.

EXPANSION OF TUBERCULOSIS ASSOCIATIONS

Harry L. Hopkins, director of the New York Tuberculosis and Health Association, discussed the question, "Should the Tuberculosis Association Go into Other Health Fields?" The rapid decline of the tuberclosis death rate and the wide increase of public facilities, such as sanatoria, clinics, health departments, and nurses, warrant the tuberculosis associations in giving serious thought to future programs. The campaign against tuberculosis has by no means been won; an aggressive warfare must be continued, but it should no longer be in the form of direct services rendered. Rather should it be to encourage public authorities to provide funds for adequate sanatorium beds, more tuberculosis clinics, more nurses, and more tuberculosis physicians. Its direct services should be limited to health education, and even here more efforts should be made to induce the public authorities to extend their own facilities. Associations can properly take part in direct activities of a research nature and more particularly those that are demonstrations in character.

Tuberculosis associations, national, state, and local, are admirably equipped to extend their efforts in combating other forms of disease and in promoting positive public health work. Among the projects that have already been undertaken by certain associations are the campaigns against diphtheria and heart disease, the promotion of mental hygiene, child health work, and social hygiene.

OFFICERS ELECTED

The officers of the National Tuberculosis Association elected for the ensuing year are: president, Dr. Alfred Henry, Indianapolis; vice-presidents, Dr. John H. Peck, Des Moines, and Dr. Willard B. Soper, West Haven Connecticut; secretary, Dr. Charles J. Hatfield, Philadelphia; treasurer, Henry B. Platt, New York City. Officers of the American Sanatorium Association, whose sessions were held simultaneously, are: president, Dr. Harry Lee Barnes, Wallum Lake, Rhode Island; vice-president, Dr. Fred H. Heise, Trudeau, New York; secretary, Dr. W. H. Ordway, Mt. McGregor, New York.

The Trudeau Medal "for the most meritorious contribution on the cause, prevention or treatment of tuberculosis" was awarded this year to Dr. Allen K. Krause.

THE RELATION BETWEEN ALLERGY AND IMMUNITY IN TUBERCULOSIS: Max Pinner (Amer. Rev. of Tuberc., 1931, XXIII, 174). The relation between allergy and immunity is the subject of many experimental and clinical studies. The term "immunity" is used by different writers with a disconcerting variety of meanings. Pinner defines it as "a condition which is in a specific way subservient to the existence of the biological entity whose integrity is attacked by a specific agent."

The following questions should be answered: is allergy desirable or not? is it instrumental in warding off infection? does it mitigate the destructive effects of reinfection? does it promote healing processes?

Fibrosis seems to occur only in allergic soil. The great frequency of healing and completely healed foci should be pointed out. "Fixation" of bacilli is instrumental in tuberculo-immunity. On the other hand only an allergic animal can be killed within a brief time by an infection with tubercle bacilli. Only in allergic soil does an infection cause acute and toxic conditions of exudative foci with rapid caseation. Whether fibrosis develops more rapidly with a high degree of allergy is not settled. Both healing and progression may proceed under the same condition of allergy. The attempt has been made to establish a quantitative relation between a phenomenon defined by its causation (allergy) and one defined by its purposive (teleological) significance (immunity). The one cannot logically go hand in hand with the other. It then cannot be decided whether immunity or hypersusceptibility is by necessity linked with allergy. It is impossible to establish a causal relation between them. Immunity depends not only on the condition of the organism in question but on extrinsic factors as well, such as dosage and virulence of the infecting micro-organisms, portal of entry, etc.

It is not permissible to ascribe all healing processes to specific immunity, for constitutional factors, environmental influences, mechanical conditions in the local lesion, and many more factors decide the clinical course.

The attempt to correlate allergy and immunity quantitatively is doomed to failure because the two are incomparable concepts. Immunity cannot be measured in terms of allergy for the same reason. The clinician should not try to correlate a strong tuberculin reaction with high immunity, nor will he find the reverse relation to hold true. The elusive nature of immunity, whose doings are obscured by many extrinsic factors, cannot be recognized nor measured until the disease has run its course.

The elimination of the term immunity from clinical usage will more clearly show the pressing need to study carefully the influence which allergy has on pathological processes. It should be possible by close clinical observation to decide definitely whether a high or a low degree of allergy influences favorably, resorption, fibrosis or calcification. The fact that the answers to such questions are not available today deprives us of the opportunity to use one possibly powerful weapon against the disease, namely, the controlled alteration of the intensity of the allergic state.

PEDIATRICS

THE MORO REFLEX AS A DIAGNOSTIC AID IN FRACTURE OF THE CLAVICLE IN THE NEW-BORN INFANT: Heyworth N. Sanford, M.D., Chicago (Amer. Jour. Dis. Children, June, 1931, Volume 41, Number 6). Fracture of the clavicle in the newborn infant is the most frequent fracture occurring during delivery. Statistics show that this fracture occurs in one per cent of all births. It may result from manipulation during delivery, but it is by no means rare in spontaneous birth, especially when the mother is a multipara.

Moro found that on placing an infant on a table and then forcibly striking the table on either side of the child, a motor reaction is obtained. The arms are suddenly thrown out in an embrace attitude, describing an arc and tending to approach one another with a slight tremor; the fingers are at first spread and then closed. Gordon in examining eighty-five infants during the first month of life found that all gave a positive Moro reflex. He thought that the absence of the embrace reflex on one side is an indication of either motor paralysis or injury on that side.

There are several conditions in which this reflex is absent symmetrically for various periods of time during the first ten days, but the author has not seen any cases in which it was asymmetrical for more than the first twenty-four hours, except in fracture of the clavicle. On the side of fracture there is no response.

In 465 new-born infants, six cases of fracture of the clavicle occurred. This was the only condition in which the Moro reflex was asymmetrical, no reflex being obtained on the side of the fracture.

R. N. Andrews, M.D.

APPENDICITIS IN CHILDREN: R. Franklin Carter, M.D., New York (Arch. of Ped., Vol. XLVIII, No. 6, June, 1931). The high mortality of acute appendicitis in childhood should be an incentive for a closer scrutiny of those patients who present symptoms of abdominal distress that may be the forerunner of the usual symptom-complex of acute appendicitis.

Primarily then, a consideration of the anatomy of the organ should be taken up. And it will be found to be a vestigial structure, subject to great variation in size, length, position, and in its relation to the ileum and cecum. The meso-appendix, in which the artery from the ileocolic vessel descends to supply the appendix, is also subject to great variation in length by which both the artery and the appendix may be affected in that the appendix may be thrown into coils or angulated at its base in case of a short mesentery and the return flow of blood hampered from pressure of the constricted vessels.

From a consideration of the anatomical peculiarities of this organ it will be seen that the stage is set for the primary step in the development of the acute appendicitis, viz., constriction of the lumen of the appendix. In view of the amount of lymphoid tissue in the appendix, any irritation is likely to cause a constriction from hypertrophy of its lymphoid tissue.

The associated nausea and vomiting of an appendicitis in the chronic stage is usually referable to eating. Frequently nausea or vomiting occurs during or immediately after eating and rarely do they occur definitely with the occurrence of the pain. It all is the result of a pylorospasm, which is a reflex from the intermittent appendicular irritation.

In the usual uncomplicated case of appendicitis, the further examination consists in a complete urinalysis, to further eliminate the kidney as a source; a complete blood count with eosinophilia determination; and a gastro-intestinal X-ray.

In addition to the acute appendices that result from the above process, there is a definite group of fulminating appendicitis cases, usually of the streptococcus type, that occur without prodromal symptoms and in which at operation the appendix may be found to have none of the developmental astigmata associated with the more common appendicitis that this paper deals with

R. N. Andrews, M.D.

THE MECHANISM OF THE KETOGENIC DIET IN EPILEPSY: E. M. Bridge and L. V. Tob (Bull. Johns Hopkins Hosp., XLVIII, 373, June, 1931): In order to test the hypothesis that improvement from the ketogenic diet parallels the tendency to remove fluid stores from the body, Bridge and Tob studied three pairs of girls subject to frequent attacks of petit mal. As a result of these studies they arrived at the following conclusions:

"Neither the ketosis nor the acidosis accompanying the so-called ketogenic treatments for epilepsy can be considered the sole beneficial factor of such regimes.

"Experiments are reported showing that if the high fat diet has succeeded in removing a surplus of extracellular fluid from the body, improvement in seizures is associated; if the diet has not removed this fluid, it has not affected the course of the disease.

“Since a simple acidosis and a sodium-free diet also end to produce similar losses of fluid from the body, asting may be considered a triple mechanism—high fat iet, sodium-free diet and acidosis—for the removal of xtracellular fluid, while the ketogenic diet has only vo factors—high fat diet and acidosis.

‘Since no ketogenic diet can be considered a failure ntil it has failed to maintain the good effects of fastng, it is believed that the institution of the high fat iet should always be preceded by a minimum of five ays of complete starvation, water only being allowed.

“Although the data presented have been obtained from hildren with petit mal epilepsy, there is no apparent eason to suppose that they do not apply to children ith major convulsions as well.”

ROENTGENOLOGY

DIAGNOSIS AND TREATMENT OF THE SO-ALLED SCIATIC NEURALGIAS: Gaston Labot, I.D., and M. B. Green, M.D., New York City (Amer. our. of Surg., Volume XI, Number 3, March, 1931, age 435). The authors review the subject of the soalled sciatic neuralgias, giving a modern method of reatment, and review ten cases, illustrative of the diferent types in which this disease appears clinically.

The so-called sciatic neuralgias include not only painul conditions of the sciatic nerves, but of the external utaneous and anterior crural nerves. It is of clinical nportance to make a correct diagnosis of the exact erves involved. For the localization of these involved reas, the authors use an electric percussion hammer.

Instead of caudal or epidural blocking, which is genrally used, the authors recommend individual blocking f the involved nerves, in this way avoiding impairment f vesical and anal sphincters, as well as weakness of oth lower extremities. Through blocking, the circulaion of the infected side is improved, giving greater omfort to the patient.

The solution used is a mixture of alcohol and neocain, nade up as follows: Alcohol 95 per cent, solution neoain 2 per cent; the above two mixed in the proportion f 1 to 4 or 5.

Physiotherapy, in the form of diathermy, infra-red ays, and massage, is generally used. The authors think that diathermy does not give as satisfactory results as infra-red rays and massage. Each case must be individualized and the different changes explained to the patient after the blocking treatment.

One big advantage of nerve blocking is that it avoids addiction to harmful narcotic drugs. This method is also used in relieving painful conditions, associated with productive osteoarthritis. The period of relief varies, and cannot be foretold in the individual case; but in general the experience with this individualized and selected form of nerve blocking has given encouraging results, and is worthy of further development.

SURGERY

COCCIDIODAL GRANULOMA — ROENTGEN DIAGNOSIS: Roy A. Carter, M.D. (Amer. Jour. Roentgen., XXV, No. 6, June, 1931, p. 715): The author presents a very complete review of the literature on this subject. Etiology, pathology, treatment, clinical manifestations, diagnosis, lesions of bone and intrathoracic involvement are each considered fully. An excellent review of the entire subject is presented. The value of roentgen examination in this disease is brought out.

The author stresses the following points. Coccidiodal granuloma is roentgenographically similar to tuberculosis. Features of pulmonary and osseous involvement will in some cases permit a provisional diagnosis between them. The association of pulmonary and extrapulmonary lesions in some cases is suggestive. The roentgenoolgist may thus promote recognition of the disease although he cannot make a positive diagnosis. The resemblance to blastomycosis is greater than to tuberculosis, and distinction would seem difficult, if not impossible. In viewing films of osteomyelitis and tuberculous-like lesions of lungs, the possibility of coccidiodal granuloma, blastomycosis and other infectious granulomata may be considered. The frequent occurrence of infectious granulomata of undetermined origin suggests a field of future study.

The article is well illustrated by many plates showing lesions both in bones and lung.

J. Sagel, M.D.

EFFECTS OF FEMALE SEX HORMONE ON CONCEPTION

Experiments on guinea-pigs, made with a view of deermining the effects of injections of the female sex ormone on conception and on pregnancy, showed that he female sex hormone is the active agent in producng estrus. In previous studies it had been found that njections of the serum from pregnant women would elay the onset of estrus in guinea-pigs. These obervations would seem to indicate an antithetic action etween the female sex hormone and the corpus luteum hormone. Other experiments have indicated that the injection of the female sex hormone into pregnant white rats would terminate the pregnancy if it had not exceeded five days. Other investigators also, using white mice, were able to prevent conception and to interrupt pregnancy at any stage with comparatively small doses of the sex hormone. With guinea-pigs small doses of the female sex hormone prevented conception and with larger doses it was possible to interrupt pregnancy and in some cases caused the death of the mother. (Jour. A. M. A., May 16, 1931, p. 1698.)

BOOK REVIEWS

Books listed here become the property of the Ramsey and Hennepin County Medical libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

TEXTBOOK OF HUMAN EMBRYOLOGY. Cleveland Sylvester Simkins, Ph.D., Associate Professor of Anatomy, University of Tennessee Medical School. 8 Vo., 436 pages of text and 263 illustrations. Price, $4.50. F. A. Davis Co., Publishers.

Professor Simkins has brought together the information up to date on human embryology. It is refreshing to one long out of medical school to take this book and find how much new material and research work has been added to human embryology. The text is done in a terse and yet comprehensive way. The work, of necessity, is a compilation from many sources, but the personality of the author carries along with you through the pages of the well written text a conviction that the work has been well done.

As the author has stated in his preface, "the rapid accumulation of information regarding physiology of reproduction in the human has created a need for a students' text that would incorporate the essential bits of information now available." This part of the text will be particularly edifying to those who have been out of the medical school ten years or more.

The author has drawn freely from all available sources illustrations which assist remarkably in elucidating the text. There is a bibliography of 252 titles which adds materially to the value of the book.

This book can be well recommended to the student and to the physician who wishes to keep abreast of the more recent work done in embryology, which may be of much aid to him in his own restricted field of medicine.

John C. Brown, M.D.

ANNUAL REPRINT OF THE REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR 1930. Cloth. Price, $1.00. Pp. 91. Chicago: American Medical Association, 1931.

This book is essentially a record of the negative actions of that distinguished body, the Council on Pharmacy and Chemistry of the American Medical Association; that is, it sets forth the findings concerning medicinal preparations which the Council has voted to be unacceptable for recognition and use by the medical profession. Many of the reports record outright rejection or the rescinding of previous acceptances; others report in a preliminary way on products which appear to have promise but are not yet sufficiently tested or controlled to be ready for general use by the profession.

Among the reports recording outright rejection are those on: Avesan (H), formerly Nuforal, a mixture stated to be composed of formic acid, sodium nucleinate, camphor, allyl sulphide and chlorophyll, with traces of salicin and sulphuric ether, marketed with unwarranted claims of usefulness in the treatment of tuberculosis, asthma, and other respiratory diseases; Ceanothyn, once before rejected and still found to be marketed with unsupported therapeutic claims; Collosol Calcium and Collosol Kaolin, so-called colloidal preparations, the former an unscientific mixture of unproved value, the latter a possibly dangerous preparation, and both marketed with unwarranted claims; Ephedrol with Ethylmorphine Hydrochloride, an unscientific ephedrine preparation marketed under an unacceptable proprietary name with unwarranted therapeutic claims; Farastan, an unscientific iodine-cinchophen preparation proposed for routine use in "arthritis . . . and Rheumatoid conditions"; Haley's M-O Magnesia-Oil, a magnesia magma and liquid petrolatum mixture in fixed proportions marketed with emphasis on the "M-O"; Lydin, a testicular extract, marketed with claims of value in the treatment of impotence; and Metatone, a shot-gun "tonic" mixture marketed under a proprietary name with unwarranted therapeutic claims.

WANTED—Salaried appointments for Class A Physicians in all branches of the medical profession. Let us put you in touch with the best man for your opening. Our nation-wide connections enable us to give superior service. Aznoe's National Physicians' Exchange, 30 North Michigan Ave., Chicago. Established 1896. Member The Chicago Association of Commerce.

OFFICE SPACE suitable for doctor and dentist. Lake of the Isles district. Before August 1st. J. R. Huntsicker, West High Pharmacy, 2755 Hennepin, Minneapolis.

WANTED—Position as hospital laboratory technician or physician's office assistant. Training in Chicago hospital. Good references. Viola Witt, Northfield, Minnesota.

WANTED—Scandinavian surgeon of thorough training and pleasing personality for Northwest clinic group. Possible permanent connection. Address D-142, care Minnesota Medicine.

WANTED—Young internist with X-ray experience for clinic group. Norwegian preferred. No investment required. Address D-141, care Minnesota Medicine.

THE DOCTOR TAKES A HAND IN VETERANS' RELIEF

C. B. Wright, M.D.
Minneapolis

A GREAT deal of interesting and significant data and opinion came to light in the course f recent discussions of the medical and hospi- lization program and policy of the Federal gov- rnment at the Philadelphia meeting of the merican Medical Association. Several speak- rs pointed out to the House of Delegates of that rganization that the present program, unless odified considerably, is likely to lead eventually a government hospital in each congressional istrict and to unlimited expenditures, increasing rom year to year as the millions of former serv- e men need medical service or hospitalization r disabilities incurred during civilian life.

It was pointed out at this meeting that all this xpenditure is justifiable only if it is for the best terests of the veteran. The preponderance of pinion was that for the veterans themselves it eld no assurance of better service than they ight receive privately from civilian physicians nd in civilian hospitals, while, on the other and, there was the very real danger of making ore and more of them into "institutionalized ases."

DISABILITY INSURANCE A BETTER METHOD

A better method of handling the situation, in iew of the fact that the government has already nbarked upon the policy of medical and hospi- l service for all veterans, regardless of the ori- ins of their disabilities, was outlined in a reso- tion submitted to the House of Delegates by r. H. H. Shoulders of Tennessee, prominent in e American legion of that state.

This resolution does not seem to be contrary any way to the avowed policy of the Ameri- an Medical Association in regard to the exten- on of free service, inasmuch as it must be as- umed that the veterans have already rendered to the government a service commensurate with any such disability policy.

The resolution submitted by Dr. Shoulders reads as follows:

"WHEREAS, The federal government has inaugurated the policy of rendering medical and hospital benefits to veterans of the World War with non-service connected disabilities; and

"WHEREAS, This policy was inaugurated over the opposition of the American Medical Association; and

"WHEREAS, The policy now in force if carried to its logical conclusions, involves the construction, the staffing, and the maintenance of a sufficient number of hospitals to accommodate the hospital needs of all the veterans of the World War; and

"WHEREAS, The present policy is of unequal benefit to veterans by reason of the fact that many disabled veterans cannot (for one reason or another) avail themselves of the benefit, therefore be it

"Resolved, That the House of Delegates of the American Medical Association petition the Congress of the United States and the American Legion to abandon the policy of rendering hospital and medical benefits to veterans of the World War with non-service connected disability, and substitute therefor a plan of disability insurance benefits with the following provisions:

"First, the creation of a Bureau of Disability insurance in the Veterans' Bureaus as now constituted.

"Second, the issuance of a disability insurance policy to each veteran with a disability benefit clause, as follows:

"(a) The payment of a weekly cash benefit during a period of total disability, and "(b) The payment of liberal hospital benefit sufficient to cover the hospital expenses of a veteran during a period of hospitalization for any disability. Such benefits to be paid to a veteran on satisfactory proof of total disability, and

"(c) Such other provisions as are necessary for the proper administration of the act.

"Be it further

"Resolved, That the proper officers of this association be instructed to approach the officers of the American Legion with the view to securing the adoption of the policy above set out as a part of the legislative program of the American Legion, and be it further

"Resolved, That each state medical association be requested to form a committee whose duty it will be to approach the state and local Legion posts throughout the country with a view to securing the adoption of this program by them."

This resolution was adopted by the House of Delegates following considerable discussion.

The American Medical Association is opposed to the policy of paternalism as applied to the care of veterans, but those of us who supported the Shoulders resolution do not believe that the insurance project as advocated by Shoulders is paternalism. It is a return by the government for a service rendered. The beneficiary is a free agent in expending this fund. Certainly this is not paternalism in the sense it might be if the government were to insist, also, on designating where the veteran should receive his medical service and from whom.

In view of the fact, therefore, that the present system establishes an out-and-out paternalism for a constantly growing class, that it is likely to undermine the morale of its beneficiaries and at the same time to cost the government untold millions for years to come, the Shoulders proposal seemed to a decided majority of the American Medical Association delegates very much the lesser of two evils.

Since the enactment of section 202(10) World War Veterans' Act which authorized treatment of all veterans in government hospitals without regard to their disabilities there has been an increase of 10,253 cases of this class within the last five years, according to an official veterans bureau statement, or approximately 2,000 per annum.

Col. George E. Ijams, director of the Veterans' Bureau, has officially remarked upon the unusual increase in medical activities of the bureau. During the first eleven months of the las fiscal year over 35,000 more out-patient treatments, 16,000 more hospital admissions and 750 000 more physical examinations had been recorded than during the previous year, he say He also points out that five new veterans' hosp tals have been completed and additional contrac hospitals have been made available.

SIX THOUSAND NEW BEDS IN FIVE YEARS, VETERANS' BUREAU OBJECTIVE

According to the official Veterans' Bureau estimate, 3,000 additional beds will be necessary i 1933, and 6,000 in 1936.

At the same time, civilian hospitals all ove the country are facing serious deficits, largel because there are empty beds in all of the amounting to approximately 40 per cent of th total capacity.

If these beds could be used by veterans, an paid for out of some such insurance policy as th Shoulders resolution suggests, the supporters c the resolution believe that present hospital def cits could be reduced, the government saved huge bill for additional hospitals and hospital a ministration and the cost of hospital care to th entire population lowered.

On the other hand, if the present policy of th federal government is pursued to its logical en such institutions for the care of all organic disease may very well be established as are foreshadowed in the cancer unit of the Edwar Hines Jr. Veterans' Hospital of Hines, Illinoi Note as evidence this interesting statement issued recently by the Hines hospital.

"It has been estimated," says the statemen "that among the veterans of the World Wa about 300,000 will die eventually of cancer, an that, in addition about 100,000 under favorabl circumstances will be cured, which means that i all probability about 400,000 veterans at one tim or another will suffer from cancer. Dr. Hug Scott, manager of the Edward Hines Jr. Hospital, estimates that probably 250,000 of these me will apply for treatment to one or another of th diagnostic clinics of hospitals. Thus the questio is very important and a start has already bee made towards its solution.

"In the central states, from Canada to the Gul of Mexico and from the Allegheny mountain to the Sierras, every veteran who is suspecte

having cancer will be sent to the Cancer Cen-
r which Dr. Scott has established at the Ed-
ard Hines hospital just out of Chicago."

Further evidence, not only of the magnitude
the present government program, but also of
e definite purpose of the government to rush
an early completion the gigantic veterans' hos-
tal building program authorized by the last
ongress is found in the following news item,
rrying a Washington date line and dated July
, distributed by a national press agency.

"Speeding up its work to provide employment
ring the depression, the veterans will complete
$20,500,000 hospital program a year and a half
ead of schedule, it was announced today.

"Under the policy of Congress of providing
spital facilities for non-service connected
ses, a policy which has brought complaint from
ganizations of American physicians, it is ex-
cted that other hospital programs will be au-
orized in the near future.

"Congress has appropriated $97,450,000 for
terans' hospitals since 1919, with the load of
tients increasing as the average age of World
ar veterans rises."

As indicated in the last paragraph, there will
a proportionate increase in the number of dis-
ilities originating in civilian pursuits as the av-
age age of the veterans rises, and it is this lat-
r type of cases that would require the con-
mplated increase in building programs.

It is obvious that the future policy of the gov-
nment in dealing with war veterans' relief is
the utmost importance to everybody. But it is
pecially important and serious to the members
the medical profession in view of the criti-
sm that has been directed toward the profes-
on in recent articles appearing in a number of
rvice men's magazines.

This criticism is prompted by misunderstand-
g of the physicians' attitude and a misconcep-
on of its aims and purposes relating to the vet-
ans' program.

"I believe," declared General Hines in discus-
ng veterans' legislation pending before the Senate finance committee of the last Congress, "that we have reached a point in connection with veterans' relief when we must give serious consideration to where we are going. It would be a pity, in my judgment, to have public opinion turned against relief measures for disabled veterans because of any unwise legislation for the able-bodied."

This, so far as it goes, is also the attitude of the medical profession.

THE THREAT TO EX-SOLDIER MORALE

But the physicians look farther than that. They see clearly the debilitating effect of a too beneficient paternalism on men who are otherwise quite fit to take a responsible, adult place in the world. They see these men taken from their homes, moved long distances for protracted stays in government hospitals, separated from their families and family responsibilities and gradually becoming the easy-going wards of the Veterans' Bureau.

At the same time they see equally well equipped and staffed civilian hospitals running at serious losses because of their thousands of empty beds—beds that could be occupied by these same men in their home towns, looked after by their family doctors. These empty beds are inevitably boosting the price of hospital care to the entire civilian population while the government continues to build hospitals and more hospitals to cope with its ever growing waiting lists of veterans.

From the very beginning the medical profession has taken an active interest in the veterans' relief program of the government. The seriousness of the question, the medical and hospital problems involved, naturally enlist the physicians' attention. That the tremendous stakes in government funds and in ex-soldier morale involved in the pursuance of the present scheme call for leadership in some new scheme of relief is the opinion not only of the physician but of many other conscientious, thoughtful people.

It may be that the Shoulders resolution will prove to be the answer to the problem.

THE SATURATION POINT*

N. O. Pearce, M.D.
Minneapolis

In the preparation of a paper, which had to do largely with the evolution of medical school teaching and its influence on modern medical practice, certain phases of economic influence bearing on the future practice of medicine came to light. Considering these to be matters of the utmost importance to the profession of the state, I have assembled a few pertinent facts which I am sure will point out the necessity for a carefully planned study of present conditions in the practice of medicine and show if possible how we may safeguard the future economic independence of the physicians of this state.

The practice of medicine, as a means of livelihood, is in many ways different from most other methods of earning a living. In a sense, the licensed physicians are what may be called a legislative monopoly. Collectively we are a great industry performing a definite task for which the people of the United States pay to us a certain aggregate sum of money yearly. The total sum has a definite limitation, which is probably basically fixed by the number of people in the country. This total medical income may be augmented by an increase in population, by a general increase in the prosperity of the country, possibly by new medical procedures, creating an efficiency in healing which would increase the demand for medical services, and further, by some plan that would assure physicians reasonable compensation for caring for those now receiving medical charity.

On the other hand, there are many influences at work which are materially deducting from the amount of medical service physicians are called upon to perform. For example,—many of the diseases which a few years ago occupied a large part of the activity of many physicians have been practically eliminated, and in the natural course of events, there will be other conditions which now form a lucrative part of medical industry which will also be eliminated. Furthermore, the education of people in health matters will eventually have a tremendous influence on cutting down the instance of disease. Also, the medically enlightened public of the future wi need much less medical consultation than in th past. So, it would seem that the influences th work today are those which will curtail rathe than enhance the earnings of the medical profe sion in the future.

Thus, a certain fixed sum of money, variousl estimated at from 450 to 600 million dollars re resents the combined annual earnings of the phy sicians of the United States. How this su shall be divided so as to give each individu physician an income somewhat commensura with his years of preparation, his capital inves ment, and long hours of daily industry and r sponsibility, is the fundamental problem whic confronts the practicing physicians individual and collectively of the United States today.

Obviously, if we take the medium sum of 50 millions of dollars annually, it would allow $10,000 income for 50,000 physicians. Ho ever, it is estimated that in this country there a at the present time two and a half times th many men actually practicing medicine for a liv lihood, which raises up the question of how ma physicians have we now in this country, and ho many do we need.

We have in this country today more physicia in comparison with population than any oth country in the world. Statistics show that in t United States there is one physician for eve 720 people. Austria comes next with 1—87 Switzerland, 1—1,250; Italy, 1—1,400; De mark, 1—1,430; England and Wales, 1—1,49 Germany, 1—1,560; France, 1—1,690; Belgiu 1—1,700; the Netherlands, 1—1,820; Swede 1—2,860; Mexico, 1—3,100; Brazil, 1—3,00 Persia, 1—25,000.

We had in the United States in 1930, 168,2 physicians—125,000 of whom were in acti practice, and 98,307 of whom were members the American Medical Association. It is some interest to note that only 62 per cent we members of our National Association, and th 73 per cent of all physicians in Minnesota we members of the State Association; while Henn pin County Medical Society has 62 per cen

---

*Address before the House of Delegates at the annual meeting of the Minnesota State Medical Association, Minneapolis, May 4, 1931.

Ramsey 67 per cent, and St. Louis 75 per cent. t is of some importance to the organized medical rofession to know just who compose the 68,000 hysicians who are outside of our medical organzations.

There are at the present time undoubtedly a reat many more physicians in this country than re necessary to adequately serve the population, nd in the past few years there has been a arked increase in the number of physicians raduating from medical schools.

ow in Medical Schools—21,597 700-1,000 yearly increase

Entered 1929-30—6,457 Applications—31,749

It will be noted (Table I) that while the med-cal schools have steadily decreased in number ince 1905, there has been a steady increase in raduates in the past ten years until, in 1929, eventy-six medical schools graduated 4,565 tudents. There are now in medical schools 1,597 students, more than at any other time in he history of the country, with an annual in-rease in enrollment of from 700 to 1,000. How-ver, a most significant and disturbing fact is that n the 1929-30 year there were 31,749 persons roperly prepared and qualified making applica-ion for entrance to medical schools, of which ,457 were admitted, and the rest refused only ecause of lack of facilities for educating them. We may very well wonder what will soon become f the practice of medicine as a means of liveli-ood if medical schools are encouraged or per-nitted to increase their capacity so as to accom-nodate all the applicants who would like to enter he profession.

Taking into consideration the number of phy-icians who are retiring and dying each year, here will have to be an approximate increase in he United States population of at least three nillion people per year in order that the ultimate ,500 yearly medical graduates of the United States will find a place in the medical field without raising our present ratio. As a matter of record, the increase in the population in the past ten years has been less than 1,700,000 per year. So figuring conservatively on the population basis, there will be twice as many physicians graduating as the normal population increase would support.

Bringing this problem to Minnesota, last year there were 130 graduates, and there were about forty deaths of physicians in Minnesota. Generally speaking, Minnesota will have to absorb the yearly contribution of her own medical school, and when we consider that there will be almost immediately at least 6,000 yearly graduates, and there are only 48 states, we will probably have to absorb at least 100 physicians per year, which on a reasonable basis of 1,000 population to the physician, would need a yearly increase in population in Minnesota of 100,000; while, as a matter of record, the population of Minnesota has only increased 176,000 in ten years.

TABLE II

UNIVERSITY OF MINNESOTA ENROLLMENT

Year	General Enrollment	Population Ratio	Law	Engineering	Pharmacy	Medicine	Dentistry
1900	2372	738	498	209	0	368	28
1905	2781	712	481	399	67	242	121
1910	3399	610	447	407	82	177	195
1915	3565	597	177	475	101	222	266
1920	7551	316	267	1213	117	385	400
1925	9858	251	285	1140	178	583	390
1930	12439	210	283	1601	152	740	272

University Increase, 425% Population Increase, 46%

This situation is probably to a large extent true in most other departments of professional education. The figures (Table II) show that in 1900 the University of Minnesota had one student to every 738 residents, while today there is one student to every 210 residents. The marked increase in the student body in the medical school is only equalled by that of the Engineering Department. The University student body, as a whole, has increased 425 per cent since 1900; while the population of the state has increased only 46 per cent. This situation in Minnesota is true also of the educational conditions throughout the country. There are today more people acquiring business, academic and professional education than the demands of the country can possibly afford to employ and unless some means are found to stem the flow of graduates from the professional schools, and especially medical schools, the doctor of the future will be hard-put to maintain economic respectability, and this is a real problem when we realize that the practicing profession no longer controls the institutions that are engaged in medical education.

Fig. 1.

It was undoubtedly fundamentally a desire to curtail the number of physicians which prompted the American Medical Association in 1906 to undertake to raise the standards and requirements for medical examination and licensure. At that time we had 160 medical schools—more than all other countries together. Some states, as for instance Kentucky, had as many as 14. There were few schools in the country which would measure up to our present standards. In the process of evolution of the medical school to its present standards, great emphasis was placed upon pre-medic education and upon the importance of fundamental scientific branches in the medical schools. This necessitated tremendous monetary outlay in medical schools for laboratory and other facilities, and was the primary factor in eliminating a great many schools and causing the consolidation of a great many others. At present, only heavily endowed private schools and those associated with great state universities are able to exist.

In the process of financing the present medical schools, it has been necessary to place these schools under general university administration. So today, we no longer have medical schools in which the teaching and administration are in the hands of the practicing medical profession, but medical schools which are under general university administration with a full time teaching staff, who, as a rule, have never had much experience or any great interest in the private practice of medicine. The great emphasis on fundamental branches and research, and the small salaries available, have divorced, to a large extent, the interest of the practicing profession in medical teaching, and medical education is now in the hands of men who have come up, in most cases, through the laboratory and research departments, which tends to isolate the medical school from the practicing profession. However, I do not ropose to go into that at this time except to ay that I am not one of those who believe that nen with this background will not make excel-ent clinical teachers provided their research ctivities do not predominate in the school to ie detriment of students and teaching facilities. t any rate, this situation has taken away from ie practicing profession any great or command-g voice in the control of the size of these chools or of the number graduated except as e may have influence on legislative appropria-ons.

Fig. 2.

The second fact of interest which appeared in ie study was the marked irregularity in the dis-ibution of physicians as based upon popula-on. An attempt was made to study the distri-ution of specialists in different cities, but the data are not accurate enough to warrant drawing any conclusions, although it is very apparent that there is a wide difference in the ratio of specialists to population in different cities. However, the data on the ratio of physicians as a whole to population by states, by counties and cities, are available and show a most interesting variation.

An analysis of this condition will be well worth undertaking as it may lead to a better distribution in the future.

We have prepared a map (Figure 1) of the United States and the figures inserted show the ratio of physician to population. One is immediately impressed with the wide variation. For example, California has three times as many physicians per population as has South Carolina.

Why should Delaware have a ratio of 935 while adjoining Maryland has only 668? And why should New York have a ratio of two hundred less than any of the surrounding states? Why are there so few physicians in South Carolina and so many in Tennessee, and so many more in Missouri? Why have Nevada and Colorado only 600 people to each physician while Idaho has 1,389, Kansas 829, and Oklahoma 996? Why have Minnesota and Michigan only 882 and 863 respectively while Wisconsin has 989 and Iowa only 770?

We might reason that because Minnesota has two large population centers, St. Paul and Minneapolis, and Michigan a large population center at Detroit, that this would explain why we have a larger number of physicians than Wisconsin, which has no large population center. But this will not explain why Iowa, with no great population center, has still more physicians per population than any of these states.

The inequality of the distribution is even more striking when one comes to study the ratio of physicians to population by counties. For example, in Minnesota (Figure 2), the number of people to each physician ranges all the way from 3,818 in Mahnomen County, down to 618 in Henneipn County, not considering Olmsted, the home of the Mayo Clinic, where the ratio is only 1 to 104. It is probable that the use of county lines is not a very sound method of judging distribution. It is quite possible that doctors are concentrated in certain large towns or rural cities, but practice more or less in adjourning counties. However, this is not the entire explanation.

For instance, Anoka County, just to the north of Hennepin County, has a ratio of 1 to 2,302; and Wright County, just to the west, has only 1 to 1,232; and Meeker, still a little further away from Hennepin County, has 1 to 1,988. In other words, many of the counties in the best rural districts, some of which are very well populated, have a great many more people per physician than some of the poorest rural districts.

Likewise in the counties surrounding Olmsted County, with its great medical center, there are on the average more physicians for the population than in any other district in the state; while in the counties around Hennepin and Ramsey there are many less physicians than in many other parts of the state. Mankato, in Blue Earth County, has one of the lowest ratios of any city I know, but there is also a comparative concentration in counties adjoining. This state distribution will require a certain amount of explanation and analysis before conclusions can be drawn.

It is interesting to note the concentration of non-medical healers in the large cities and the rather even distribution throughout the rest of the state. The small letters represent the number of chiropractors in each county. They seem to bear no definite relation to the number of physicians in the various communities. Minneapolis is blessed with 163 chiropractors while St. Paul, with more than half the population, has only forty-nine.

A study of some forty-five cities with medical schools and forty-five cities of as nearly as possible equal population without medical schools, disclosed that the average ratio in medical school centers of population to physicians was about 100 less than in nonmedical school cities. However, there is a great variation in cities containing medical schools which is not entirely dependent upon schools or upon population.

For instance, in Washington, D. C., with a half million population, the ratio is 1 to 282; in Boston with three-quarters of a million people, the ratio is 1 to 332; St. Louis, with three-quarters of a million population, has a ratio of 1 to 426; Chicago, with three million, has a ratio of 1 to 511; Philadelphia, with two million, has a ratio of 1 to 541, and Cleveland, with one million, has a ratio of 1 to 645. So while the tendency is for the medical student to settle in the community where he has acquired his education, there are other factors involved in the distribution.

A further study was made of forty-five cities, fifteen with a population of over 300,000, fifteen between 100,000 and 300,000, and fifteen from 30,000 to 100,000. The selection presented on this chart (Table III) has a wide geographical distribution, and while the total number of cities actually canvassed were great in number, those presented are typical examples of the whole.

Of the large cities, we again have Boston with a ratio of 1 to 332; Kansas City with 1 to 391; Indianapolis, a city of almost identical size, with 1 to 485; Baltimore, more than twice as large, with 1 to 520; Minneapolis with 1 to 545; Milwaukee, with a hundred thousand more inhabi-

TABLE III

RATIO OF POPULATION TO PHYSICIANS IN 45 CITIES

Population 300,000 and over		Population 100,000 to 300,000		Population 30,000 to 100,000	
Washington, D. C.	282	Nashville	333	Oklahoma City	279
Boston	332	Denver	337	Lexington	302
San Francisco	358	Portland, Ore.	424	Lincoln, Neb.	379
Kansas City	391	New Haven	456	St. Joseph	408
St. Louis	426	Omaha	459	Columbia	418
New York City*	450	Richmond, Va.	461	Augusta, Ga.	420
Indianapolis	485	Hartford, Conn.	478	Fort Smith	452
Chicago*	511	Oakland, Calif.	485	Macon, Ga.	594
Baltimore	520	Salt Lake City	552	Wichita	616

Seattle	595	Norfolk, Va.	742	Galveston	730
Milwaukee	643	El Paso, Texas	775	Ogden, Utah	751
Cleveland*	645	Duluth	834	Oshkosh, Wis.	772

*Over 1,000,000 population

tants, having 1 to 643; Cleveland, more than twice as large, with 1 to 645.

Coming to the second group (100,000 to 300,000), the range of the ratio is not strikingly different except that it tends to be considerably higher in many of these cities. Taking El Paso, Texas, for instance, with a population of about 117,000, with a ratio of 1 to 775. We find about the same range in cities of from 30,000 to 100,000—Oklahoma City with 1 to 279; Oshkosh, Wisconsin, with 1 to 772. Why Nashville, Oklahoma City, Denver, Lexington and Lincoln, Nebraska, should have such a low ratio, and why Tulsa, Charleston, Norfolk and Galveston, should have such a high ratio, are questions presenting problems which are worthy of some investigation.

A further study (Table IV) of the situation in Minnesota in particular, with reference to some of the larger and smaller cities, and a comparative study of the ratio between city and rural physicians in Minnesota, gives one much interesting information. I was considerably surprised to find that of all the larger cities in the country, Minneapolis, while far from being the best, is just as far from being the worst. In spite of the steady influx of physicians to Minneapolis, the ratio of physicians to population has not materially changed in the past twenty years.

You will note a ratio of 1 to 538 in 1912, and a ratio of 1 to 548 in 1929. St. Paul has not been quite so fortunate. In 1912 their ratio of 1 to 709 was much greater than that of Minneapolis. It is now down to 1 to 636, but still almost a hundred more people per physician than Minneapolis. Duluth with the exceedingly high ratio of 1 to 808 in 1912 has come down to 1 to 725 at the present time. There are almost 200 more people to each physician in Duluth than in Minneapolis. Just why this situation should prevail is not entirely clear. Here again is a point for study which should bring some information of material value.

TABLE IV

RATIO OF PHYSICIANS TO POPULATION IN 1912 AND 1929

		1912			1929	
	Population	Physicians	Ratio	Population	Physicians	Ratio
Minneapolis	301,408	560	538	464,356	847	548
St. Paul	214,744	303	709	271,606	442	636
Duluth	78,446	97	808	101,463	140	725
Rochester	7,844	55	143	20,621	397	52
St. Cloud	10,600	13	815	21,000	33	636
Mankato	10,365	28	370	14,038	36	390
Winona	18,583	21	885	20,850	22	948
Four Cities	602,462	1,015	593	858,046	1,826	475
Rural	1,473,246	1,247	1,181	1,705,907	1,258	1,355
Total	2,075,708	2,267	911	2,563,953	3,084	882

A cursory study of three of our largest cities outside of the four shown above, shows a wide difference of population to physician. It will be noted that in 1912 St. Cloud had a ratio of 1 to 815. In spite of a large increase in population in the past seventeen years, the ratio is now down to that of St. Paul, and much lower than that of Duluth. Mankato, for some reason unknown to me, had in 1912 a ratio of 1 to 370, and with a moderate increase in population of 4,000 in seventeen years, has still maintained about the same ratio which is now 1 to 390, one of the lowest, if not the lowest in the state for a city of anywhere near its population. On the other hand, Winona, a city situated in the very best of Minnesota's farming country, and with an old wealthy population, had a ratio in 1912 of 1 to 885, and with a modest increase of 2,000 there has been only an increase of one physician, and the Winona doctor is now in the rather unique position of being only one physician to 948 people.

A composite study of the four principal medical centers shows that in Duluth, St. Paul, Minneapolis, and Rochester in 1912, there were 1,015 physicians and a ratio of 1 to 593, while in all the rest of Minnesota there were 1,247 physicians with a ratio of 1 to 1,181. Now in 1929, the population of the cities has increased 256,000, while the number of physicians has increased 810, reducing the ratio for these four centers to 1 to 475. The influence of Rochester here is obvious. But what is more interesting and significant is that the rural population increased practically the same amount while the physicians have only increased a few more than one hundred, and the ratio of rural physicians to population has risen to 1 to 1,355. In other words, of approximately 800 physicians who have come into Minnesota since 1912, 700 have settled in the cities and only 100 outside of these cities, while the population increase in rural Minnesota is almost as large as the population increase in the four cities. This is of especial interest when we consider that the amount of work referred from country districts to the Twin Cities is estimated to have dropped from 33 to 50 per cent in the last ten years.

The income of physicians in the cities is also greatly influenced by the large number of nonmedical healers and by the many free clinics. It is estimated that in a city the size of Minneapolis, 25 per cent of all medical service is rendered by the physician without pay.

We have so far discussed the number of physicians in relation to the population and the distribution of physicians. These things are of importance mostly as to their direct bearing on the physicians' income.

Any attempt to study the earnings of physicians is fraught with much difficulty. No single study that I know of has ever been complete enough to warrant drawing any sound conclusions. Not long ago, an article in our daily papers quoting Dr. Palmer Johnson of the University stated "that the income, over the past thirty years, of university graduates who received degrees, ranged from $1,722 to $7,791, and that the physicians were at the top of the list." This statement was misleading because I believe it only referred to physicians on salary, but in any event, as you will remember, there are 168,000 physicians in the United States, and this study and the results are based on the replies to the questionnaires of only 400 physicians.

A questionnaire study in 1929 of the West Virginia State Medical Association, which is said to have been answered by a majority of the members, showed an average gross income of $9,580.60 with a net income of $6,414.43, the largest net income being $28,000, and the smallest $420. This is a state with a ratio of 971 people to each physician.

A questionnaire prepared about the same time by the Hennepin County Medical Society, which was answered by 169 out of 550 members, gave an average income of $10,300, with an average expense of $3,400, and a net income of $6,900. The figures of these studies vary so much with the figures derived from the study of the estimated total medical income, that one is forced to conclude that physicians of from medium to small earnings do not, as a rule, answer these questionnaires, and that with the comparatively small number replying, a few of the largest incomes have undue influence in raising the general average. In the past two or three years, estimates have been published of the total medical income for the United States. These estimates have varied from $600,000,000 per year by a report, the source of which is unknown to me at this time, to one two years ago of 500 million by the Metropolitan Life Insurance Company, and one, the most recent, as given out by Mr. Paul Benjamin, secretary of the Committee of Fifty, of 450 million dollars. Now then, let's take 500 million as a medium figure. Dividing that sum by the 125 thousand practicing physicians gives us $4,000 as the average gross medical income. With an average overhead of 30 per cent, this would leave an average net income of $2,800 (Table V).

Table V

PHYSICIANS' EARNINGS IN RELATION TO COSTS OF SICKNESS PER YEAR IN UNITED STATES

Patent Medicines and Drugs	$700,000,000
Physicians	500,000,000
Hospitals (civil)	380,000,000
Nurses (all forms)	200,000,000
Dentists	150,000,000
Non-Medical Practitioners	50,000,000

125,000 physicians dividing $500,000,000 = $4,000 each
Average overhead 30% Net average income $2,800
Allowing 30 day vacation Employed 335 days
$2,800 for 335 days = $8.35 per day

Should we allow a thirty day vacation period, a physician would have 335 working days. This would give an average daily net income of $8.35. Just where the medium income of physicians should be placed is hard to decide. It is probably considerably higher than the figure represented here, but undoubtedly a great deal lower than would be indicated by some of the studies already mentioned.

It is interesting to notice the 700 million spent for patent medicines and drugs, the tremendous amount being paid in hospital bills, the enormous amount now being paid to nurses, the comparatively smaller sum to dentists, and the 50 million dollars that goes to the non-medical practitioner.

Table VI

MINNESOTA NON-MEDICAL PRACTITIONERS

	Chiropractors	Osteopaths	Midwives	Masseurs
1928	493	162	111	268
1929	486	160	101	214
1930	462	165	95	200
1931	451	162		
Minneapolis	161	49	21	39
St. Paul	49	22	22	89

There has been apparently a tendency for chiropractors to leave the state (Table VI). We still have the same number of osteopaths as we had four years ago. We have not investigated records previous to the time of the Basic Science Board, but it is quite evident that the heroic efforts of our legislative committee in passing the basic science law has put an effective stop to the influx of nonmedical healers in Minnesota. And, if we will back up our legislative committee in its efforts to prevent legislation which will break down this defense, we can look forward to the time when there will be few osteopaths and fewer chiropractors in Minnesota and the other still worse types of healers will be entirely eliminated.

There are a great many influences which are now at work which have a direct bearing on medical income. Some of these are new and hard to evaluate.

Table VII

INCREASE IN MEDICAL AND NURSING PROFESSIONS IN UNITED STATES

	Physicians	Nurses
1900	122,167	11,804
1910	135,317	82,327
1920	145,608	149,128
1930	168,201	214,751
	Graduated	
1930	4,565	18,000

In 1900 (Table VII) there were 122,167 physicians and 11,804 trained nurses in the United States. The increase in physicians was 13,000 in the first ten year period, 10,000 in the second ten year period, and 23,000 in the last ten year period. On the other hand, the nurses increased 71,000 in the first ten year period, 67,000 more in the next ten year period, and 65,000 in the last ten year period, until today, with 168,000 physicians, we now have 214,751 graduate nurses. In other words, there were four graduate nurses in 1930 to each graduate physician.

Dr. Olin West said recently that "we have gradually succeeded in raising the standards of nurses' education until they are now 'pretty good doctors.' " We realize, of course, that many thousands of these nurses are not actively engaged in the nursing profession. However, many of them have gone into public health fields and are doing work which is very nearly medical, and in not too few instances, directly in competition with physicians. The trained nurse is potentially a source of fairly sound, cheap, medical information. It cannot be assumed that because many of these women are no longer practicing their profession that they are not still a very prolific source of free medical advice. How many thousands of sick people are saved the expense of a physician's service by the free advice of the public health nurse, the school nurse, the insurance nurse, or by the sister or neighbor upstairs who is a trained nurse, cannot be estimated. But this huge number of medically trained people creates a problem never before met in history and is worthy of profound consideration on the part of the medical profession.

The influence of free clinics on medical earnings presents another problem which is mostly of importance because of the rapid growth of this sort of free medical service, which, in most instances, is not promoted or controlled by the medical profession. The chart shows that we had 600 free clinics in 1910, and it is estimated that there are now 6,000. A study made in New York City, with a population of six million people, showed that 1,250,000 people visited free clinics, making the total visits 6,000,000. If this group of people had been compelled to make some provision for medical care, even the small amount of $1.00 for the year, it would have augmented the income of physicians in this area by one million and a quarter dollars.

The interest of the lay public in medical matters has been greatly enhanced in the past few years. Seldom do you pick up a newspaper that does not contain from one to four, or more articles, pertaining to some phase of medical practice. The great amount of time lost due to sickness and injury has aroused the interest of industry.

The company physician is becoming an integral part of the personnel of a great many industrial organizations. This may be the first step toward the encroachment of business organizations in the field of medicine. It is estimated that 42 million people are gainfully employed in the United States. Each employee loses on an average of eight days a year as a result of sickness or accident. This results in a loss of 350 million working days, which, with the death annually of 500,000 workers, results in an estimated annual loss of $1,800,000,000. The estimate of $1,000,000,000 of this which could be saved to industry by proper medical advice and care, to me is grossly excessive. We are given credit for altogether too great an ability in the preventive field, which may eventually be to our own undoing. Certainly mediocre work and the care of the injured will not be long tolerated by either the employer or the insurance company.

There is much to be said about the corporation practice of medicine and undoubtedly the cost of illness could be greatly reduced by better organization of medical practice. Our present scheme of caring for the sick is to the people ruinously expensive. The physicians are directly responsible for making many medical paupers.

Our 7,000 hospitals, with an investment of three billions of dollars, are only exceeded in industry by iron and steel, textiles and their products, chemicals and allied products, and food and kindred products. There were only 2,070 hospitals in 1900. This number has increased 200 per year since that time. In 1909, the estimated bed capacity was 421,065. In 1928 the bed capacity had reached 892,924, and today is well over a million.

Too many physicians naturally raise the cost of medical care. Unnecessary medical procedures and unnecessary visits are a natural result of scrambling to make a living. Undue competition tends to unnecessary and over-elaborate office equipment, and a small number of patients does not allow an adequate spread of overhead.

Studies of 150 medical clinics in this country, most of which are in the middle west, tend to show no increased cost to the patient and a decidedly increased income to the physicians in these clinics. The cost of care of the sick by the government, while in many ways extravagant, is very much less than could possibly be made to pay by the private physician. One of our great local institutions is able to give adequate daily care for 600 sick and convalescing patients at a medical expense of $55 per year per patient. Unless the medical profession can organize itself so as to eventually decrease the cost of medical care, there is no doubt but that there will be a great increase in the number of individuals accepting medical charity, or lay organizations will come into the field with proper organization and provide medical service at a very much lower cost than that which prevails today with very considerable profit to themselves.

Just one more step and we will have institutions established and thoroughly equipped and operated by lay people, managed by lay people, for profit, with doctors on a salary basis.

Perhaps the most eminent and important influence working into the practice of medicine at this time is that represented by health, injury and compensation insurance.

Most of the states have at this time some form of compulsory accident compensation insurance, but none so far has developed a compulsory sickness insurance. It is not necessary in this paper to discuss the different plans of compensation surance except to say that the plan varies reatly in different states. The important point physicians is that it assures them a fairly dequate fee for the care of the injured. In 930, there was paid to physicians in Minnesota 2,100,000 by insurance companies, and this represents 37 per cent of the entire disbursement this state under this act. In this type of inrance the compensation feature outweighs the st of medical and hospital care. So, insurce companies are interested in getting the best ssible surgical service and the tendency is to y reasonably well.

Our legislative committee have fought and won strenuous battle in this present legislature to aintain the right of the patient to select his own ysician. However, the insurance companies ill not tolerate incompetence or neglect in the re of the injured, and it is only a matter of me when they will hire their own physicians a stated salary to do this work in the large nters at a much reduced cost to themselves. oluntary health insurance is rapidly on the inease in this country. In 1926, there were 0,000 such policies, and in 1930, 2,000,000 alth and accident policies covering 85 per cent medical, hospital and nursing expense. While is is a move in the right diretcion, it is unfortuate from our standpoint that the people who are rrying this insurance are not the ones who are dinarily objects of medical charity. Undoubtlly, in the near future, some form of compulry health insurance will be enacted, and we ust be well prepared, indeed, if we are to have y commanding voice in the drafting and enactg of such legislation. This is a world-wide ovement, and if it will in some way provide a eans by which the poorer classes are compelled insure themselves against becoming objects of arity, medical and otherwise, when they are ill injured, it will undoubtedly be of great value.

However, in every scheme of health insurance w in existence, the compensation to physicians r service rendered is pitifully small as comared with what we now receive, and in most untries compulsory health insurance is not mited to the poorest classes but includes many ho are well able to pay adequately for medical rvice.

You will note (Table VIII) that Germany was e first country to establish this plan of insurnce and it goes back to 1883, while France is the last one, starting their scheme in 1929. The League of Nations in its International Labor Bureau Report of 1927 approved and recommended that all countries adopt some plan of compulsory health insurance. Mr. Paul Benjamin, secretary of the committee of fifty, when here, stated unofficially that he thought that some plan of insurance would be recommended in the report of this committee as a means of lessening the burden of the present medical cost. Dr. West said, in regard to the same committee, "I can venture no prediction, I can only promise you that if I can prevent it, no socialistic schemes will be advocated, but I am, of course, only one of a committee of fifty to sixty members."

TABLE VIII

COMPULSORY HEALTH INSURANCE

Germany	1883
Hungary	1891
Norway	1909
Great Britain	1911
Bulgaria	1918
Portugal	1919
Poland	1920
Japan	1923
Chile	1924
France	1929

Today more than half of the German population is participating in health insurance schemes. Of the physicians in Germany, 80 per cent are deriving all or part of their income from panel patients; 15 per cent are salaried physicians; and only 5 per cent of the German physicians are practicing independently. The ratio established in Germany by the insurance companies indicates that there should be one physician to every 1,350 people.

It is most interesting to note that with 40,000 physicians working in the German panel, there are 27,000 civilians in the administration department, and, incidentally, the large incomes are in this group only. The ridiculously small earnings of the physicians of this system is illustrated by the fact that the care of a patient for one month in Danzig is less than the price of a hair cut and massage.

In England the situation is somewhat better. Only the workers, and not their dependents, are permitted to participate in the panel, and only those services which could be considered as work of general practice are included in the regular fee. All major operations and work of specialists must be paid for, or is paid for, by a special additional fee. They consider from 900 to 1,500 people an adequate group for a panel physician, the patient in all cases having a right of selection. The amount of $2.25 per year is paid to the physician for all persons who register with him regardless of whether or not they are in need of medical service.

These insurance schemes are great levelers. They insure the younger and less successful man at least a reasonable amount of work although the compensation is comparatively small.

I would like to further discuss the details of the operation of these schemes for medical care, but time does not permit. We must assuredly be prepared for the proposal of some such scheme in this country. In most other countries, no matter on what high ideal the scheme was originally established, it has sooner or later become a political football and the medical profession has been hard-put to remain to any degree in control of their own activities.

In closing, let me sum up in a few words:

We have already more physicians in this country than are necessary to adequately and econon ically care for the sick.

Our medical schools are rapidly increasing tl annual output of physicians.

The present distribution of physicians is poor systematized and tends to undue concentration

Too many physicians raise rather than lowe the cost of medical care.

Just ordinary common sense and busine acumen would prompt any great industry to car fully survey the market for its product, and hol production down to a point when supply will n exceed the demand so that it can be assured c a ready market at a reasonable return for th output. This is what we should do today.

The medical profession, as well organized as is in Minnesota today, can and should undertak a careful and detailed study and analysis of th situation of the medical profession in this stat and, through its splendid organization, shoul take such steps as are necessary to protect th future practice of medicine as a means of livel hood.

THE FEDERAL FOOD AND DRUGS ACT

1906-1931

A quarter of a century ago, on June 30, 1906, President Theodore Roosevelt signed the Food and Drugs Act specifically designated "for preventing the manufacture, sale, or transportation of adulterated or misbranded or deleterious foods, drugs, medicines and liquors and for regulating traffic therein, and for other purposes." This measure has had a wholesome effect that can scarcely be realized by those not familiar with the conditions of the past. The American Medical Association, through the Council on Pharmacy and Chemistry, has been a pioneer in its efforts to protect the medical profession and the public against fraud, undesirable secrecy and objectionable advertising in connection with proprietary medicinal articles. Its efforts have been greatly facilitated by the passage an enforcement of the Food and Drugs Act. The comin of age of the Food and Drugs Act should not be a lowed to pass without some reference to the dominar figure in the crusade for pure foods and drugs, th late Dr. Harvey Washington Wiley. He was chic chemist of the U. S. Department of Agriculture durin the period of the fight for the federal act, and unt 1912, "a very mountain amoung men, a lion amon fighters." The movement that he helped to start deserves unqualified commendation. The forces on th fighting line deserve congratulation. There is still muc to be accomplished. Vigilance must never be relaxe (Jour. A. M. A., July 4, 1931, p. 32.)

PARESIS AND MALARIA[*]

George N. Ruhberg, M.D.
Saint Paul

INCE 1917 the results obtained in the treatment of paresis have not only shown a ssened mortality, but have returned an in- easing number of patients to economic re- very. This is encouraging when compared with sults formerly obtained. Von Jauregg's work introducing malaria for the treatment of this sease has not only given us a most valuable ethod of treatment, but has stimulated work in e treatment of syphilis by non-specific means, hich in time may produce something more valu- le than malaria itself.

In the majority of cases the spinal fluid is tered by reduction of cells; by diminution in tal protein; often by reduction in the strength the Wassermann reaction, and a modification reduction in the colloidal gold curve. Clinical- the results are at times startling, at other nes disappointing, but on the whole the remis- ons have been more lasting, the mortality less, d the incidence of economic recovery mark- lly increased. The usual reported clinical re- veries from different studies by recognized thorities have ranged from 25 to 50 per cent. must be remembered that these cases are prac- cally all advanced to the degree of requiring spital care, showing unmistakable mental mptoms and are economically totally incapac- ated.

Pathologically paresis is characterized by ickening of the dura and pia arachnoid; a attening and atrophy of the convolutions, es- ecially of the frontal and parietal lobes, with me thinning of the cortex and loss in brain eight. There is increased vascularization of the rtex, and perivascular infiltration with round, lasma and mast cells. There is also a generalized roliferative glial reaction, and the nerve cells ow all stages of degeneration. Inflammatory actions are also found around groups of spiro- etes within the substance of the brain. Areas f softening are also found secondary to peri- d endarteritic changes. There is considerable isorganization of the cortical layers and disap- earance of the tangential and association fibers. Degenerative changes may also occur in the basal ganglia, brain stem, and in the cerebellum. Jacob has pointed out that in paresis the tissue fails to react with sufficient strength against the spirochete and thus fails to produce the typical gumma, or characteristic granuloma. The miliary gummata occasionally found are considered by him to be specific and successful reactions against the infection. When this infection is severe, or the reaction weak, the process becomes malignant, and is represented by the non-specific diffuse reaction of paresis.

Spielmeyer has emphasized the important conception of two fundamental types of lesions found; the vascular (mesodermic) and parenchymatous (ectodermic). He has also emphasized the independence of these two types, and the importance of considering them separately in studying and comparing the pathological and clinical findings after treatment with malaria.

Just how malaria acts on the paretic brain has not been definitely settled. Freeman reported that during the early stages of treatment the inflammatory reaction appears to be exaggerated. He also believes that there is organization of the perivascular exudate, and finally a reconstruction of the cortical laminations. Many authorities have denied an exacerbation of the process, as well as the existence of a "healing inflammation." Straüsler and Koskinas described the regression of the pathologic process and a stationary appearance of the lesions, comparable to the picture of stationary paresis described by Alzheimer. They interpreted their findings as due to the non-specific and malignant forms of the paretic reactions undergoing a change into a more benign form. Kirschbaum thought that the malaria acts by simple reduction and moderation of the inflammatory exudate. Ferrarro from a study of twenty-nine paretic brains concluded that the beneficial influence of malaria was chiefly exhibited in its effect on the inflammatory reaction. This change consisted in diminution of the exudate, and in the reduction of the new blood vessels. Its influence on the parenchymatous changes are less definite, but in favorable cases the beneficial influence is evident on both ectodermic and mesodermic reactions. He found no parellelism between the clinical course and the vascular reactions, but he did find a rough parallelism between the clinical course and the a subsidence of some of the parenchymal reactions.

---

[*] Thesis presented before the Minnesota Academy of Medi- ne, February 11, 1931.

In considering the subject of paresis it is necessary to consider the sequence of events following the intial infection. Brown and Pearce have shown experimentally that within a few days spirochetes may be secured from the heart, blood and lymph glands of rabbits. Dissemination of the organism probably takes place from the lymphatic system to the peripheral blood stream. From the blood stream they seek more favorable surroundings and after a second period of incubation in their new locations the tissues react with the secondary outbreak. At this time the immune reaction takes place. With the regression of the secondary lesions, the vast majority of organisms are killed by this natural defense. This immunity may prevent the organisms harbored in the lymph glands from being thrown off, or it may destroy those that later escape from these foci. The duration of this process varies from three to twelve months, and from then on the disease is latent. The *Treponema pallidum* probably is not neurotrophic, but involves the central nervous system by vascular routes as a consequence of the general infection. The spirochete has been demonstrated in the spinal fluid with otherwise normal spinal fluid findings. The same phenomenon has been demonstrated in rabbits. The reason for the incidence of neurosyphilis probably is accounted for by the nature of the soil on which infection takes place. Brown and Pearce have suggested that all tissues are not equally protected by the general reaction which occurs during the early stages of a syphilitic infection, and that certain tissues, which fail to receive this protection, may be capable of only a slight degree of self-protection. They believe that this holds true for reactions in experimental animals, and that this local immunity, or lack of it, may explain the incidence of neurosyphilis in man.

Filder, Maitland and Parnell in a study of 1,314 cases of early syphilis found a pleocytosis in the spinal fluid in 14 per cent during the primary stage, in 21 per cent during the late primary, and in 30 per cent up to eighteen months following infection. The spinal fluid Wassermann reaction was positive in 3 per cent of the late primary cases, and in 6 per cent up to eighteen months. Fordyce and Moore also found in their series that the time of involvement of the central nervous system reached its maximum by eighteen months following the initial infection From then on the disease is latent, and is known as latent, or asymptomatic neurosyphilis. In some cases the disease may never again become clinically active. However, should such a patien die at any time, a thorough microscopic examination will reveal the presence of small latent lesions which vary greatly in degree and extent Warthin has stated that in no case of latent neurosyphilis has he found an absolutely inactive syphilitic infection. In nearly 100 per cent of these cases he found focal lesions in the meninges. There is apparently a slow progressive development of spirochete localization, with healing and fibrosis. They are found most frequently over the parietal, temporal and frontal lobes According to Warthin they vary greatly in size and show every degree of transition between mild fibrosis to clinically active and more extensive involvement of the meninges. In the brain he found small localized areas of perivascular infiltration, similar to those found in the lesions in cases of paresis and cerebral syphilis. They are usually few in number, and very small in size, and they are found most frequently in the neighborhood of the frontal and parietal lobes, and especially in the neighborhood of the ventricles. The important consideration in latent, or asymptomatic neurosyphilis, is that active, progressive, pathological changes are present in the central nervous system as a consequence of syphilitic infection.

It is readily evident that the only means of diagnosing latent, or asymptomatic neurosyphilis, is by examination of the spinal fluid. For this reason no patient should be discharged from treatment of acute syphilis without such an examination. The ideal situation would consist of spinal fluid examination during treatment, and within a reasonable period up to five years following. The presence of an early positive fluid is a serious thing, and the failure of the profession at large to recognize this fact constitutes, in my opinion, one of the major reasons for the prevalence of clinical neurosyphilis. As a rule, the more marked the fluid changes, the longer it takes to reduce it to normal. Also the more marked the fluid changes, the more serious is it to the patient. Usually the ordinary methods of treatment are sufficient for minimal and intermediate changes. However, the treatment should be guided by fluid findings, and many cases will require more intensive treatment than others.

In this consideration it is interesting to note Moore's findings in insufficiently treated cases of latent neurosyphilis. He found that inadequate treatment caused an increase in the group showing the paretic formula. This may explain the earlier onset and, according to Nonne, the increase of paresis following the introduction of salvarsan. It is with this group of cases showing the paretic formula, a four plus Wassermann a paretic gold curve, increased cells and globulin, that we are particularly interested in this discussion. I know of no large group of cases of latent syphilis of this type which has been adequately studied. It is essential that titered Wassermann reactions be done; that colloidal gold, or similar reactions, be used to bring out the paretic curve, and definitely separate this group from ordinary asymptomatic neursosyphilis. I am unaware from a search of the literature of such a study having been done in a large group of cases extending over a period of a decade. When we consider that paresis usually exhibits itself clinically fifteen to twenty years after infection, the need for further investigation of the fate of these individuals showing the paretic formula is realized. In a series of thirty-six such patients under Moore's observation for only eight years, only 27 per cent can be regarded as clinically and serologically well; thirty-three per cent have developed clinical neurosyphilis, and in 40 per cent the status is questionable; seven have developed paresis, and three tabes. It was found that the usual methods of treatment were of no avail, and those that did show a satisfactory fluid reduction took on the average forty months' intensive treatment, and in many malaria and tryparsamide were needed. This excellent but unfinished study by Moore of a small group of these cases, over a comparatively short time, gives an indication, at least, of the serious prognosis and grave danger of subsequent ruination by parenchymatous neurosyphilis.

The early asymptomatic cases are in the hands of the syphilographers and general profession. The majority still go unrecognized as such. The neurologist, as a rule, does not see them until many years later, when clinical signs are evident, and in many the destruction has progressed to such an extent that cure, or even alleviation, is frequently impossible. If results are to be improved, these cases must be diagnosed and treated earlier than at present. It is essential that not only clinical results be obtained, but that the serology be reduced to normal if possible.

Just when paresis begins is extremely hard to determine. Theoretically speaking, the preparetic stage extends from the time of initial infection until the frank appearance of paresis. The first stage is asymptomatic or latent; the second stage has been described by Jellife as neurasthenic. During this stage neurasthenic symptoms appear with very fine gradations of personality and conduct changes. The correct diagnosis of this stage is paresis sine paresii. After a variable period of time the mental symptoms make their appearance, and it is in this period, usually fifteen to twenty years after the initial infection, that the diagnosis is made and serious treatment begun.

The treatment of paresis may be said to be an attempt to prevent as much as possible parenchymatous destruction in the brain. Logically to do this most successfully the attempt must be made before destruction has markedly progressed. In other words, we must recognize the potential case and treat it accordingly. Because I believe that malaria is, at present, the most effective method in treating paresis, I advocate its use in all suitable cases of neurosyphilis showing a paretic formula which fails to reduce after a reasonable trial with the usual methods. The following cases are illustrative:

CASE REPORTS

Case 1.—A male, aged 43, married, was first seen in May, 1925. He had had a chancre twenty years previous. He had the usual secondaries, and received inadequate treatment. In 1922 he noticed his left hand closed on him occasionally while working. In August, 1923, he suddenly became unconscious. On coming to, he was drowsy and his left arm was paralyzed. He recovered the use of his arm and hand in a few days, and since then has had no recurrence of these spells. He stated, however, that when he got nervous he lost some control of the left hand, and it would shake. He suffered frequently from headaches during the last two or three years. He had no girdle or lightning pains, and had no trouble in handling the legs. In 1925 he made an application for and was refused life insurance. He then consulted the late Dr. Sweeney and myself on May 6, 1925.

On examination his pupils did not react to light. The right was larger than the left. Test words were well enunciated. The strength in the right and left upper extremities was equal. The abdominal and cremasteric reflexes were present. The right knee jerk was one plus; the left three plus. Achilles reflexes were both present. There was no clonus or Babinski; the coordination was good, and the fundi were normal. Spinal fluid examination showed cells 45; gold sol. 4423120000; Wassermann 4 plus; globulin positive; blood Wassermann 4 plus. He received active and continuous treatment until December 12, 1927, when the spinal fluid showed cells 18; Nonne ++; Wassermann ++; mastic +; gold sol. 5555540000; blood Wassermann negative. His subjective symptoms in the meantime had cleared up, and he felt well. He was discouraged about the results from two and a half years continuous treatment, for although some improvement was obtained in reducing somewhat the strong Wassermann reaction, yet the gold curve was unmistakably stronger in the paretic zone, and the fluid on the whole showed the paretic reaction.

In January, 1928, he was inoculated with malaria. He had ten paroxysms, during which his temperature varied from 103 to 106. He made an uneventful recovery, and returned to work in April, 1928. His health improved, he gained ten pounds in weight, and he stated eight months after the malaria that his health was better than it had been in years. On September 2, 1929, spinal fluid cells were 2; Wassermann negative; globulin a trace; gold sol. negative; blood Wassermann negative. In September, 1930, the fluid continued negative, and he is in good health.

At no time could this man have been diagnosed as a clinical case of paresis. Dr. Sweeney and I thought he was a potential case, and that there was grave danger of his later developing paresis. For this reason, when prolonged treatment of tryparsamide and arsphenamine failed to reduce the fluid to normal, he was given malaria. It accomplished the desired results, and so far, at least, he seems to be out of danger. With a negative fluid, his chances of escaping this fate are probably much improved.

Case 2.—A single man, aged 43, admited a gonorrheal infection fifteen years previously. For the past two years, he had had several spells during which he developed a weakness of the left arm and leg. He also said his head felt "wooden" at times, and he said he noticed that his memory was rather poor, and he would have trouble in concentrating on his work. He was rather apprehensive during these spells, which would last for a few days, and at one time he had the fear that he was going to lose his mind. He consulted his doctor, who made a diagnosis of neurosyphilis, and gave him treatment with arsphenamine and bismuth for a year and a half. He was referred to me for examination in September, 1929. The pupils reacted sluggishly to light. There was an internal strabismus of the left eye. His speech was normal. There was a slight tremor of both hands. The right optic disc was somewhat pale. Spinal fluid showed Wassermann 3 plus; gold sol. 555543000; globulin one plus; cells 18.

His mental reactions seemed slightly sluggish to me, but he showed no memory defects to recent or past events, nor any malignant mental signs. He was somewhat apprehensive about losing his mind, and he stated that mental work was harder for him. Treatment with malaria was advised. This was given in November, 1929, and he had five severe chills, accompanied by marked prostration. His blood pressure went from 130 to 90, and the treatment was then terminated with quinine. He made a prompt recovery, and returned to work in January, 1930. His health was improved, and he was elated over the results of the treatment. He told his physician that he was better than he had been for the last four or five years. I reëxamined him in October, 1930, and found his pupils reacted promptly, the strabismus remained the same, there were no tremors, and the examination was otherwise negative. The spinal fluid was examined by the same laboratory as formerly, and it was reported normal.

This man had developed a hernia in July, 1930. In November, 1930, he had this hernia repaired. Unfortunately, he developed pneumonia a few days following operation and died. An autopsy could not be obtained. This is also a case of neurosyphilis showing a paretic formula of the spinal fluid, which was reduced by malaria when the ordinary methods failed. At no time could a clinical diagnosis of paresis have been made.

Case 3.—A man, aged 29, consulted me December 6, 1928, complaining of occasional dizzy spells during the past two months. He also complained of occasional pain in the back of the neck, nervousness and fatigue. He gave a history of a chancre seven years ago, and during the year following he stated he had pain in the back of the neck. He received inadequate treatment. The present pain reminded him of the previous one, and he thought there might be some connection between the two.

The physical examination was negative. I found his pupils reacted to light and accommodation, and from an objective standpoint a diagnosis of asymptomatic neurosyphilis could be made. His spinal fluid showed Wassermann 4 plus; cells 52; gold sol. 5555542000; globulin 2 plus. He received thirty-eight treatments of tryparsamide, and about the same number of bismuth. In May, 1930, the blood Wassermann was positive. The gold curve was still strongly paretic; the spinal Wassermann was 4 plus; and cells 18; globulin 1 plus. During this course of treatment his subjective symptoms improved somewhat as far as the dizziness and pain were concerned. However, he still had spells of fatigue, and afforded a typical neurasthenic picture.

He was given malaria in June, 1930. In December, 1930, he reported that he has been working steadily since August, and that he felt much better. He is not suffering from so much nervousness and seems very grateful for what has been done for him. A spinal fluid examination on December 31, 1930, still shows a strongly positive fluid. The only improvement being noted is a reduction of cells from 18 to 4, and a 2 plus globulin reduced to a slight trace. The Wassermann reaction and colloidal gold remain the same as they were six months ago, prior to the malaria. He has had no other treatment since he had the malaria, but his spinal fluid finding will be checked at least yearly if possible.

Two of these cases were unmistakably neurosyphilis from a clinical standpoint. One is of the asymptomatic type from an objective sense. There was nothing characteristic about his complaints. In all three strong paretic type fluids were found, and the usual methods of treatment were unavailing after a fairly reasonable trial. Malaria reduced the spinal fluid findings in two, and has partially reduced the third within six months. They illustrate the type of case which, in my opinion, is best suited for malarial therapy, which constitutes the ideal method, for the present at least, of treatment of paresis. I am perfectly aware that perfection will never be obtained in the treatment of this disease, but the least we can do is to strive for the ideal. It may be occasionally possible to accomplish this by the method of treatment above described.

Final conclusions, of course, cannot be drawn from an investigation of three cases of this type. However, it may be concluded that to diagnose the more serious form of asymptomatic and symptomatic neurosyphilis, thorough spinal fluid examinations are necessary. Furthermore, these fluids are exceedingly hard, and often impossible, to reduce by ordinary treatment, but malaria can often accomplish this when other methods fail. Finally, it must be concluded that to derive the maximum benefit the treatment of paresis must be instituted before much parenchymal damage has been done. In order to accomplish this, the use of malaria in those cases which are in grave danger of later developing the disease, is advocated.

NEW MENINGITIS ORGANISMS DISCOVERED

A new group of epidemic cerebrospinal meningitis germs has been discovered at the National Institute of Health at Washington during studies conducted under the direction of the United States Public Health Service. This is the fifth group of these dangerous germs to become known.

During the last five years there has been more of this infectious disease in the United States than at any time since the World War. A wave of epidemic cerebrospinal meningitis has traveled slowly across the United States from the Pacific Coast, Dr. Sarah E. Branham, engaged in meningitis research at the National Institute of Health, said in remarking on the discovery. This wave manifested itself in severe outbreaks in many centers of population—as, for example, in Salt Lake City, Chicago, Memphis, Detroit, Indianapolis, Philadelphia, and New Haven.

The new group of meningitis germs was found while Dr. Branham and her co-workers were endeavoring to find an improved serum for the treatment of this disease. They were engaged at the time in examining more than 400 cultures from epidemic cerebrospinal meningitis collected from various sections of the country where flare-ups had appeared.

Outbreaks of cerebrospinal meningitis often seem to be spontaneous and are sometimes widely separated, Dr. Branham pointed out, because only a few individuals out of many persons who may carry the germs of spinal meningitis in the respiratory tract actually may contract the disease. These carriers, though, may spread the infection.

The germs of this disease are grouped according to "strains." Not all strains are alike in their power to produce the disease. Some are very virulent and deadly and more apt to cause a fatal form of the disease than other strains. More than 50 per cent of the cases in the recent epidemics of cerebrospinal meningitis have been fatal in some localities, while in other cities the deaths have been fewer.

Although primarily a disease of children, epidemic cerebrospinal meningitis affects adults also, especially those living under crowded conditions and following a radically changed routine of life. Such conditions aided widespread and fatal outbreaks of epidemic cerebrospinal meningitis during the World War among soldiers encamped in this country and abroad.

Although the "meningococcus," as this germ is called, was discovered by Weichselbaum in 1887, the fact that all strains were not alike was first recognized by the French bacteriologist, Dopter, in 1909, and recognition of the first four groups of cerebrospinal meningitis germs was made by Dr. M. J. Gordon, a British physician, and his co-workers, during the World War. The majority of the "strains" sent to the National Institute of Health during the recent epidemics in the United States have been found by Dr. Branham and her associates to fall into the four groups of Gordon. The new fifth group has been found to be predominant in some parts of the Middle West.

THE PATHOLOGY AND PATHOGENESIS OF OCULAR MELANOMATA*

Walter E. Camp, M.D., F.A.C.S.
Minneapolis

THE term melanoma is used in the present study to designate all pigmented or pigmentiferous (potentially pigmented) tumors which are primary in the various coats of the eyeball. Such a group includes pigmented and unpigmented nevi of the ocular conjunctiva; pigmented and unpigmented sarcomata of the iris, ciliary body and choroid. In the older literature these tumors of the uveal tract were called leukosarcoma and melanosarcoma.

Ocular melanomata form a part of a larger group of pigmented tumors which are also found to be primary in the skin, meninges, rectum and adrenals. The bizarre appearance of this entire group, including those of the eyeball, is well known. In their histological appearances they may simulate a sarcoma, carcinoma, angioma, endothelioma and nephroma or hypernephroma. It is because of this pleomorphology that the pathogenesis of the ocular melanomata has been and still remains in a large majority of cases quite obscure.

EPIBULBAR MELANOMATA

Epibulbar pigmented tumors usually develop in situ in the bulbar or palpebral conjunctiva. In some cases, however, the growths in this location are due to extraocular extension of an intraocular pigmented tumor.

Primary epibulbar melanomata or nevi are congenital and benign but may become highly malignant. In structure and appearance they are very similar to nevi of the skin. Nevi of the conjunctiva most frequently occur in the bulbar conjunctiva just posterior to the limbus. In the majority of cases they are heavily pigmented, but in rare instances show little or no pigment even after study with serial sections. Grossly the nevi are black or reddish-brown spots of variable size. They are always smooth and may be flat or slightly raised and gelatinous looking.

In their histological appearance the conjunctival nevi resemble very closely those of the skin. The conjunctival epithelium is prolonged downward into the underlying connective tissue in the form of cords or club-like expansions which form a network or (as it appears in sections) nests of rounded or polygonal cells—the so-called nevus cell. In many instances the nests of nevus cells are surrounded by numerous small blood vessels and blood spaces, giving the appearance of an angioma or vascular nevus. In other cases cystic spaces of variable size are formed in the cords or nests of nevus cells, forming a cystic nevus. Pigmentation is quite marked in the majority of cases. The granules of melanin are found both intra- and extra-cellular. The surface or outermost layer of cells usually shows more pigmentation than the deeper layers.

Owing to the polymorphic nature of the nevus cell, its origin has furnished a problem of long debate. Unna, Post, Wieting, Dawson, and Broders and McCarthy believe that the nevus cells have their origin from epithelium. Ribbert, on the contrary, believes the nevus cells have their origin from the pigmented branching connective tissue cells or chromatophores of the corium. Recklinghausen believes they have origin from the endothelial cells of the lymph vessels.

Dawson, in his recent monograph on the melanomata, shows very clearly, both in the cutaneous and conjunctival melanomata, the origin of the tumor cells from the rete cords of the surface epithelium. The basal cells of the rete cords proliferate and form intraepithelial cell nests. These nests enlarge, break through the basement membrane, and form club-like expansions which grow down into the underlying connective tissue in anastomosing cords, forming a reticulum of tumor cells. In its subsequent development the melanoma usually assumes one of three forms.

1. The cell nests grow down into the underlying connective tissue, retain their round or polygonal shape. arrange themselves in an alveolar or acinous grouping resembling an epithelioma or carcinoma.

2. The cell nests break up and form a syncitium of elongated branching cells resembling a sarcoma.

---

*Thesis read before the Minnesota Academy of Medicine, at its regular monthly meeting of March 11, 1931.

3. The cell nests form a syncitium of branch- g elongated cells which become permeated by ew formed capillaries simulating an endotheli- na.

The majority of congenital nevi of the con- nctiva, like those of the skin, remain benign d undergo fibrosis and degeneration. The ree preceding forms just described represent ocesses which may develop as a result of ma- gnant change. Other characteristics of malig- ncy are increase in size of the tumor, increased scularity, hyperchromatic nuclei, and numer- s mitotic figures.

INTRAOCULAR MELANOMATA

Intraocular melanomata have their origin in e tissues of the uveal tract, *i.e.*, the iris, ciliary dy, and choroid. In rare instances primary elanotic growths have been described as aris- g in the sheath of the optic nerve. The intra- ular melanomata are usually primary, a search the literature revealing only three instances metastatic melanoma reaching the eye by me- stasis from cutaneous melanomata. The most cent of these was reported by Cordes and Hor- r at the last session of the American Medical ssociation. In all of these metastatic cases the es became involved as a part of a generalized elanosis.

Nevi or benign melanomata of the iris are not frequent. They may involve any part of the is, but are more commonly situated near the pillary margin. They may be single or mul- ple, and are of variable size. Grossly they ap- ear as flat pigmented spots or small circum- ribed tumors.

Microscopically nevi of the iris resemble very osely those of the conjunctiva and skin. The evus cells may simulate those of carcinoma, sar- ma, or endothelioma. Since there is no epithe- um on the surface of the iris, the origin of these evi has furnished considerable discussion. napp in 1869 described a circumscribed new owth in the iris consisting of branching anas- mosing cells, mostly pigmented, which he ought developed from the chromatophores nor- ally found in the iris. Fuchs and Anargyros escribed diffuse, deeply pigmented tumors in e iris stroma which they believe develop from e pigment epithelium of the iris. These most equently are located at the pupillary margin the iris, where two layers of the secondary optic vesicle unite. A marked proliferation of the pigment epithelium in this region is normally present in the iris of the horse.

These melanotic spots in the iris are practically always benign and remain unchanged for years. Occasionally, however, they become malignant and develop into tumors which in most cases resemble sarcomata. Rare examples in which the tumor cells resemble endothelioma and carcinoma are described. In our collection we have one specimen of a well developed circumscribed nevus which shows beginning malignant change.

Primary malignant melanoma or so-called sarcoma of the iris is rare. According to Fuchs only about 6 per cent of all malignant melanomata involving the uveal tract are found in the iris; 9 per cent are found in the ciliary body and 85 per cent in the choroid. The iris is frequently involved secondarily by direct extension of melanomata from the ciliary body and occasionally from the choroid. Primary malignant melanotic tumors of the iris are usually of the diffuse type, as contrasted to the globular circumscribed growths of a similar nature which involves the ciliary body and choroid.

It has been shown by Treacher, Collins, Ewetzky, Hirschberg, Hosch, Whiting, and others that many of these malignant tumors of the iris develop from congenital nevi which have been quiescent for many years. Dawson believes that malignant melanomata of the iris can develop from any of the pigmented tissues of the iris. This would include the chromatophores, the pigment epithelium and congenital nevi. From a study of the literature and from a study of the specimens at our disposal, it is evident that only rarely can it be shown that these tumors arise from the pigment epithelium of the iris.

While the majority of malignant melanomata of the iris are diffuse growths, occasionally they are nodular in character and quite vascular. In some instances the growth may form multiple nodules scattered through the stroma of the iris. These in all probability represent localized metastases through the blood vessels or lymph spaces. In rare cases the tumor may spread diffusely throughout the entire circumference of the iris forming a so-called annular or ring sarcoma. Annular malignant melanomata of the iris are very rare. The first reported case was by Solomon in 1882. Since that time only eight similar cases have been reported in the literature. One of these cases was reported by Dr. W. R. Murray in the American Journal of Ophthalmology for 1927. I had opportunity to make a rather complete pathological study of the eye in this case and for this reason wish to report it in detail.

The case is that of a farmer boy, nineteen years old, who came to the University Hospital complaining of gradual loss of vision in the left eye for a period of three weeks. His parents had noticed a change in the color of the iris in this eye about one year previously. There was no history of injury and there had never been pain or discomfort at any time.

Examination showed a mild injection of the bulbar conjunctiva and anterior ciliary vessels. The anterior chamber was very shallow; the pupil was dilated and immobile. The iris showed scattered areas of deep pigmentation extending from the root of the iris to the pupillary margin and involving its entire circumference. The pigmented spots were of variable size, and were not raised above the level of the surface of the iris. The lens showed a few pigment spots on its anterior surface. There was deep glaucomatous cupping of the optic disc and secondary atrophy of the optic nerve. The intraocular tension was 45 mm. Hg. Vision was reduced to light perception. The right eye was normal and had normal vision. The eyeball was enucleated and showed the following gross and microscopic pathology: Gross diameters of the eyeball were about normal. The cornea was clear. The anterior chamber was very shallow. The pupil was dilated and oval in outline. The iris was thickened in its peripheral portion and adherent to the cornea throughout its entire circumference, completely obliterating the filtration angle. There were no circumscribed nodules to be found in the iris. Pigmented areas were present on the surface of the iris extending from the periphery to the pupillary margin. The lens was slightly pushed forward, but was clear except for a few pigment spots on its anterior capsule. The vitreous was clear; the retina and choroid appeared normal. The optic disc was deeply cupped.

A portion of the eyeball was embedded in paraffin and a portion in celloidon and serial sections cut at intervals of 10 to 15 micra. The corneal epithelium, Bowman's membrane, corneal stroma, and endothelium were normal. The conjunctival vessels at the limbus were congested but there was no chemosis nor evidence of epibulbar extension of the growth. The root of the iris was uniformly thickened and adherent to the cornea for a distance varying from 0.5 to 1.5 millimeters. The thickening of the iris was due to a diffuse tumor involving the entire circumference of the iris and extending onto the posterior surface of the cornea and also for a short distance into the ciliary body. The tumor was composed of round and spindle-shaped cells, many of which were deeply pigmented. In some places where the cells were more densely packed there was a tendency to alveolar formation. There were a few mitotic figures present. There wer no giant cells, hemorrhage or necrosis. The tumo cells extended into the meshes of the pectinate ligament and into the ciliary body for a short distanc In a few sections the tumor cells were found extending into the sclera along the anterior ciliary vein The ciliary body was thinned and atrophic. The opti disc showed deep glaucomatous cupping and secondar optic atrophy. The diagnosis was annular malignan melanoma of the iris involving the cornea and ciliar body; secondary glaucoma; secondary optic atroph The origin of the tumor cells in this case could not b ascertained, but from the character of the cells an the history of slow onset, it was probable that th growth developed from a preëxisting congenital nevu or possible multiple nevi.

About 9 per cent of all intraocular malignan melanomata are found in the ciliary body. In th vast majority of cases the tumor assumes a circumscribed globular shape or becomes pyramida in outline, resembling the shape of the ciliar body itself. In rare cases the tumor is flat an infiltrating in character and may encircle in par or entirely the circumference of the ciliary body similarly to that just described in the iris. Onl about fifteen cases of annular malignant melanomata of the ciliary body have been reported i the literature.

Melanomata of the ciliary body practically always involve the adjacent iris and choroid by direct extension. When the growth is located i the posterior portion or flat part of the ciliar body it is often difficult to determine whether i originated in the ciliary body or choroid. Retina detachment, which develops so early in choroida melanomata, comes very late or not at all in ciliary melanomata, especially when the tumor is located in the anterior part of the ciliary body.

The majority of ciliary melanomata are pigmented. These form the group of so-called melanotic sarcomata. Pigmentation is due to the presence of brownish-black granules of melani found both in the cell cytoplasm and intercellula stroma. The cell types in the pigmented tumor are similar to those unpigmented. The degree o pigmentation and its distribution vary considerably. In some cases only a few cells are pigmented, while in others the whole tumor is s deeply pigmented it is difficult to study the cel structure. In other cases one portion of the tumor may be entirely free of pigment, while another is heavily pigmented.

About 85 per cent of all intraocular malignan melanomata have their origin in the choroid ey may originate in any portion of the cho- id, but are much more common in its posterior lf. Fuchs states that 85 per cent of the choroi- l melanomata are posterior to the equator of e globe. The majority of choroidal melanoma- are circumscribed rounded growths that break rough the lamina vitræ (Bruck's membrane) d fill the greater part of the vitreous cavity. om its point of origin the tumor spreads lat- ally, forming a lenticular or disc-shaped owth which gradually thickens and ruptures e glass membrane. After reaching the vitreous amber the tumor grows more rapidly and ex- nds into a mushroom-shaped mass, pushing the tina forward. The retina early become de- ched by serous exudate over an area consid- ably larger than the tumor. Finally complete ial separation occurs. Occasionally the retina comes invaded by a rapidly growing tumor.

In rare instances choroidal melanoma develops a flat diffuse infiltrating growth involving a ge area of the choroid, but forming no circum- ribed growth. Owing to the flatness of the owth, the retina is usually not separated until ry late, and the lamina vitræ remains intact. is type of growth is similar to the annular or g tumors found in the iris and ciliary body.

The histology of choroidal melanomata is very milar to that of the ciliary body. Some of these owths show numerous new formed blood ves- ls and large blood spaces. These are often lled angiosarcomata. Due to their rapid owth, when once they rupture the lamina vit- e, necrosis is commonly found. In some cases e greater part of the tumor may be necrotic.

The minute structure and cytology of malig- nt melanomata varies considerably, not only in fferent tumors, but also in different areas of e same tumor. In the literature most classifi- tions are based upon the shape and arrange- ent of the individual cells and their degree of gmentation. Fuchs, in his monograph on tumors the uveal tract, enumerated fourteen types. erschbaumer listed six, while Lagrange recog- zed two main groups: (1) the pigmented and on-pigmented sarcomata; and (2) the endothe- l sarcomata or tumors supposedly originating the endothelium of the perivascular lymph aces.

In the rapidly growing, circumscribed tumors, e predominating cells are spindle-shaped, often osely packed together, with little or no pigment, and a goodly number of mitotic figures. This type of tumor is the leukosarcoma of the old literature and closely resembles sarcoma found in any part of the body. The cells are elongated or fusiform in shape, of variable size and have a large chromatic nucleus. The cells are closely packed, with little or no stroma, and form bundles which interlace in various directions. In the smaller group of tumors the predominating cells are rounded or oval with blunt processes. The cells vary greatly in size, and when closely packed may be polygonal. Some tumors exhibit both spindle and round cells, forming a mixed cell type. In all of these types a few scattered multinucleated cells may be found. In rare instances, however, giant cells are abundant.

The origin and nature of the pigment in melanotic tumors has been the subject of long and elaborate investigation and much debate. It has been conclusively shown, I believe, that melanin is a direct result of cell metabolism. It is usually free from iron and sulphur, but rapidly unites with these elements, and for this reason may in some instances give the iron reaction. It occurs in granular or rod-shaped masses, both in the cell, and in the intercellular stroma. That melanin is a product of oxidation of its precursor melanogen which occurs as colorless granules in the cell cytoplasm is a generally accepted fact. Hibbert, Schieck, Gilbert and others have shown that unpigmented melanomata become pigmented when exposed to sunlight or through other processes of oxidation. The melanin in the urine in cases of melanuria is manifest only after oxidation of the melanogen.

All intraocular melanomata show, in their development, four stages of growth. The first stage represents the early development of the growth before the onset of secondary glaucoma. The second stage is that of secondary glaucoma. The rise of intraocular pressure is due to one of two causes: (1) a blocking of the normal filtration angle, either by tumor cells or by forward pushing of the lens and iris; (2) by obstruction of the vortex veins by direct pressure of the tumor. The preglaucomatous period may last from one-half to two years, depending upon the degree of malignancy of the growth. During this period there is usually no pain or other symptoms except loss of vision. The glaucomatous period usually lasts for only a few months and is accompanied by pain and symptoms of secondary inflammation. The third stage is that of extraocular extension, which in the case of flat, diffuse or infiltrating growths may come very early. Melanomata of the iris and ciliary body usually show extraocular extension along the anterior ciliary vessels which perforate the sclera at the limbus. Tumors in the posterior half of the ciliary body and choroid show extraocular extension along the vortex veins which are located at the equator of the globe. Tumors in the posterior half of the choroid show extension along the optic nerve and the posterior ciliary vessels and nerves which perforate the sclera around it.

The fourth stage is that of metastasis. Metastasis may come very early, even before the onset of secondary glaucoma. In other cases the metastasis may come very late. Cases are reported where metastasis has occurred eighteen years after enucleation. Metastasis is always by way of the blood vessels. The neighboring lymphatic glands are never involved. Local recurrence after enucleation is uncommon. In the older literature Parvel reported nine local recurrences in eighty-nine cases. In more recent years the percentage of local recurrences is much less, probably due to earlier diagnosis, *i.e.*, before the onset of extraocular extension.

The most frequent site for metastasis is in the liver. Most cases show, however, multiple metastases involving the liver, lungs, stomach and other viscera. Metastatic melanomata may involve any organ or tissue in the body and quite a few cases of generalized melanosis have been reported. The metastatic growths frequently have little resemblance to the original tumor. The cells may be large, vacuolated and unpigmented, resembling those seen in nephroma or hypernephroma. They may assume the character of epithelial cells or of connective tissue cells, simulating either carcinoma or sarcoma.

I wish to describe a case of malignant melanoma of the choroid in which we were able to make a rather complete pathological study.

The patient, a housewife, aged 54, reported for examination, complaining of gradual loss of vision in the right eye following an injury twenty years previous. For the past three years the right eye has been totally blind. She had had no acute pain but at intervals the eyeball had been red and tender. The left eye was normal with normal vision. About two months ago she noticed a small shot-like lump in the scalp and one in the skin over the ribs on the right side of the chest. These nodules were hard, freely movable, and slightly bluish in color. During the next few weeks
she noticed similar nodules developing in the axill
groins, and in the skin of the abdomen. She had
cough, no loss in weight, and felt perfectly well, exce
for the symptoms described above.

Examination of the eye showed injection of the co
junctival and anterior ciliary vessels. The cornea w
normal. The iris was thin and atrophic and push
forward against the cornea, obliterating the anteri
chamber. The pupil was irregular and eccentric a
showed no reaction to light. The lens was cataracto
preventing an ophthalmoscopic examination. The
was no light perception present. Tension was 60 m
Hg. as compared to 20 mm. Hg. in the left e
Transillumination of the globe showed the outer h
opaque. Examination of the sclera showed a round
bulging mass perforating the sclera in the upper a
outer portion near the equator. Aside from the sk
nodules described above, the general physical exam
nation was negative.

A diagnosis was made of malignant intraocul
melanoma with multiple skin metastases. This was co
firmed by biopsy of one of the skin nodules and en
cleation was done. Microscopic sections of the eyeb
showed a large melanotic tumor involving the choro
and ciliary body, and showing extraocular extensio
both at the equator, along the vortex veins, and al
posteriorly along the optic nerve. Large areas of t
tumor were necrotic and showed deep pigmentatio
The tumor cells were both round and spindle-shape

Six months after the enucleation the patient r
turned for examination. Her general physical cond
tion was good. The liver was not palpable and the
was no weight loss. Examination of the urine f
melanogen was negative. The skin nodules had i
creased in size and new ones formed at various plac
over the body. The socket of the enucleated e
showed a small, red, fleshy growth which on biop
proved to be an orbital recurrence. During the fo
lowing nine months the patient gradually failed; t
liver and spleen became enlarged and nodular. Dea
occurred fifteen months after enucleation. Autop
showed generalized melanosis involving practically a
of the viscera and serous surfaces.

The possible origin of the tumor cells in mel
nomata of the choroid is a question which h
long been discussed. Fuchs believes they ha
origin in the chromatophores of the extern
layers of the choroid—the layers of Sattler an
Haller. Ribbert agrees with this view and pr
poses the name chromatophoroma. Knigh
working with Broders at the Mayo Clinic, pu
lished a paper in 1924 in which she argues th
the pigment found in the chromatophores of th
choroid is phagocytised by these cells and is n
a product of their metabolism. She believes th
melanin is a product of the epithelial cells, pro
ably the pigment epithelium of the retina, an
that melanotic tumors of the choroid are to b

sidered as having their origin from ectoderm s and should therefore be called melanocarci- ia. Dawson, in his monograph on melanoma- describes thirteen cases of choroidal melano- a. In twelve of these he was convinced that tumors originated from the chromataphores the vessel layers of the choroid. In the re- ning case, which showed great diversity of cture, he described the tumor as arising from hexagonal pigment epithelium of the retina. vson also agrees with Knight and Broders the so-called chromatophores of the choroid derived from the pigment epithelium of the ia and are therefore to be considered ecto- mal and not mesodermal in origin.

wing, in his treatise on neoplasms, is inclined the opinion that these melanotic tumors of uveal tract may arise either from the pig- it epithelium or the chromatophores. He is convinced, however, that the chromatophores epithelial in origin. In ciliary melanoma he nd a splitting off of the heavily pigmented al epithelial cells.

From a study of the specimens at our disposal it would appear that the epibulbar growths take origin from the basal cells of the conjunctival epithelium similar to the process which occurs in the cutaneous nevi. The melanotic growths in the iris and ciliary body may arise directly from the pigment epithelium, or, as is more frequently the case, from the chromatophores in the vessel layers. The origin of the chromatophores is uncertain, but certainly the large, rounded, heavily pigmented "clump" cells found in the vessel layer of the iris near its pupillary margin are derived from ectoderm. In all of our specimens of choroidal melanomata the tumor cells apparently had their origin from the chromatophores. In no case was the pigment epithelium of the retina disturbed except by secondary invasion of the tumor. The possible origin of choroidal melanoma from congenital epithelial cell nests or "rests" which may become irritated by inflammation or injury cannot be disproven. A history of malignant melanoma developing in an eye long blinded by inflammation or trauma is quite frequent.

IRON AND COPPER IN THE DIET

here have developed evidences that certain minerals ch occur in small quantities in natural foods enter the nutritive exchanges of the organisms in ways e important than has heretofore been believed. many years claims of the biologic significance of a ıber of such elements have been heard. They are ost inevitable contaminant of foods, so that it has extremely difficult to determine decisively whether , nickel, cobalt, manganese, copper and others are ice constituents of the animal organism, or whether or more function in some essential process. Re- ly attention has been focused on one of these ele- ts by the discovery that copper possesses the prop- of supplementing iron in forming hemoglobin in certain types of experimental anemia. Nutritional anemia can apparently be best corrected in several species by the addition of copper as well as iron to the defective rations. There also is considerable evidence that important functions are performed by manganese. Many analyses of foods concerning the mineral content have become available so that the daily intake of these elements may be judged. Wheat bran, blueberries, whole wheat, split peas, and navy beans are rich in manganese. Calf liver, oysters, beef liver, mushrooms, currants and chocolate are rich in copper. Pork liver, beef liver, spinach, lima beans, calf liver, and navy beans are rich in iron. Vegetables and cereals are the chief contributors of iron. Fruits are an important source of all three elements. (Jour. A. M. A., July 18, 1931, p. 180.)

THE AMERICAN RITE—TONSILLECTOMY*

W. W. Lewis, M.D.
Saint Paul

APPROACHING closely in breadth and extent of practice the Jewish rite of circumcision, tonsillectomy on infants and near-infants as carried on in America today will soon be in the lead. Fortunately, like other excesses of bygone days, it will be just as precipitately repudiated when the pendulum of rational consideration begins its return swing and its enormity of error is realized.

If Mother Nature ever amplified her protest against misdirected surgical interference, it is most forcefully manifested in her almost desperate effort to replace this lymphoid-glandular tissue of which she has been robbed, which is so unmistakably a necessary part of the lymphatic system of defense and probably, too, of the internal secretions in all young mammalian creatures.

The picture, in these little post-tonsillectomized throats, of multiple hypertrophied buds of lymphoid tissue sprouting out from all over the surface of the posterior pharyngeal wall, and the pillow-like masses of lymphoid accumulations in the lateral pharyngeal folds, only too plainly shows Nature's heroic effort to replace this lost tissue. The rapid regeneration of the tiniest islands of follicular tissue left in the tonsillar fossæ and the plica tonsillaris into almost "new tonsils" attests plainly to the proof of the need for this glandular-lymphatic tissue in the throats of these youngsters during infancy and childhood, at least up to the age of puberty, at which age, normally, these lymphoid structures begin to recede in size and importance of function.

The practically unbroken tonsillar ring of the lower animals, comparatively present in humans, also, made up of the lingual tonsils, the faucial tonsils and the nasal tonsils, certainly indicates the importance of the function of these structures. Reports have appeared in the literature of experiments upon lower animals where part of the tonsillar ring has been removed, following which the health of these animals, observed for periods of time, showed marked deterioration, terminating in severe anemia and marked d bility.

Just as certainly as the lower animals, wh use their mouths in working, fighting, dressin their wounds and making their toilet, need pr tection against infection in the oral cavity, s young humans, too, need the same protectio during the period of life when everything withi reach goes to their mouths.

Every region of the body is protected by definite localized arrangement of the lymphati system, and surely the oral cavity can be no e ception, where in reality it would seem to b more needed than in any other region of th body.

The indications for tonsillectomy universall accepted are: Hypertrophy with obstruction prolonged local inflammatory disease in the tonsi as indicated by continuous cervical gland involv ment; glandular dyscrasia, a perverted or hyper secretion of the tonsils which unfavorably affect the child's general ruggedness; and systemi poisoning from focal infection.

Tonsillectomy as a whole problem should b divided sharply into three groups for best con sideration, because the indications in thes groups are considerably different one from th other.

Group I. Tonsillectomy in infants and near infants.

Group II. Tonsillectomy in children (pas infancy) up to the age of puberty.

Group III. Tonsillectomy in subjects pas the age of puberty.

In the last group, especially after adolescence tonsillectomy is done largely on account o systemic poisoning from focal infection; less s on account of recurring local acute inflammator disease; least of all on account of hypertroph with obstruction; and not at all on account o glandular dyscrasia.

In the second group, children (past infancy up to the age of puberty, tonsillectomy is don largely on account of hypertrophy with obstruc tion; also on account of glandular dyscrasia ich unfavorably influences the nutrition or wth of the child; less so on account of pro- ged local inflammatory disease with cervical nd involvement; and least of all on account of temic poisoning from focal infection.

---

*Read before the Minnesota Academy of Ophthalmology and Otolaryngology, Minneapolis, March 13, 1931.

n considering the first group (infants and r-infants), let us eliminate practically all of indications universally accepted for tonsil- tomy as a whole and mentioned, also, in con- ering each of the other groups named.

ystemic poisoning from chronic local and al infection in the tonsils of infants surely is to be considered as a probability nor as a son for tonsillectomy.

ecurring local acute inflammatory disease of tonsils occurs but rarely in infants as com- ed with older children, youths or adults. It is, vever, a fortunate defensive reaction when it s occur, and to remove these lymphatic first- e fortifications seems to me poor practice.

Hypertrophy of tonsils in infants (that is, real pertrophy, not merely congested, temporarily ollen tonsils) must, indeed, be a rarity, and glandular dyscrasia of older childhood (five ten or twelve years of age) is surely not to considered as occurring in this group.

The role of the thymus, rapidly terminating er birth, suggests an important part played by sil-gland structures as internal secretory or- ns in developing creatures, and its function in natal life probably compares closely with the essity for glandular-lymphoid-tissue function youngsters from birth up to puberty. The essity for the functioning of each seems to limited, comparatively, to certain respective iods of development, after which periods re- sion of function is manifested by atrophy, nplete in the thymus and relative in the tonsils.

Nor are development and hyperdevelopment of s glandular-lymphoid tissue limited to the l and nasal surfaces. Other exposed mucous mbrane surfaces (namely, the conjunctivæ) quently show during childhood overdeveloped nphoid tissue. The so-called follicular con- nctivitis, really lymphoid hyperplasia, is, too, tinctly a condition limited to life prior to berty.

Tonsillectomy in adults, generally speaking, is dom done without justification. In the first ce it is always considered in connection with me complaint of the patient, either systemic local, for which he is seeking relief. If a systemic malady, his case has been gone over thoroughly by his physician. Much thought, usually, has been put forth, possibly by several consultants, and a fair unanimity of opinion reached before he, himself, consents to the recommended procedure. If of a local character, his complaint is nearly always of repeated occurrence sufficiently severe to lead him to a fixed determination to rid himself of such recurrences. As a result, to repeat, seldom is tonsillectomy done in adults without full justification.

In youth the same and corresponding general conditions obtain, and, again, we can almost as certainly say tonsillectomy is seldom done in patients of this age without justification.

When we come, however, to tonsillectomy in children, between the age of infancy and puberty, as a group and in general, no such certainty of justification can be assumed. In the great majority of children at this age, tonsillectomy is done routinely, without much consideration, independent of and indifferent to consultation, with little thought, I think I can safely say, further than to arrangement of time and place, acquiesced in by parents, "following the leader," and for no greater reason than that the child next door has had his tonsils out, and it seems the proper thing to do.

At this age, in cases of glandular dyscrasia, comparable to hyperthyroidism, where the child seems to be held back in nutrition, growth and general ruggedness, no more remarkable improvement and favorable results are accomplished anywhere than by tonsillectomy.

In the occasional cases of systemic poisoning, manifested by chorea, arthritis, and so forth, tonsillectomy also brings relief when the focal point is correctly located.

Tonsillar hypertrophy (that is, real hypertrophy) with obstruction is also an acceptable reason for tonsillectomy in growing children, because such an hypertrophied structure, taking on much of a fibroid or scar-tissue infiltration, is relatively an incompetent gland, and, leading up to subsequent atrophy, affords little of the protective function of the normal or near-normal tonsil.

Unfortunately, much of the so-called hypertrophied tonsils in children of this age is not genuine hypertrophy at all, but is merely congested and swollen tonsils putting up their normal defensive reaction against infection, after which siege they rapidly return to their normal size and character. To remove such tonsils as these is to deprive the child of the most vital first-line fortification of his lymphatic defense-system in this region. Repeated congestion and swelling of the tonsils, over and over again, do lead to real hypertrophy, with an accompanying decline in the competency of the gland.

We have, then, in this group, two justifiable reasons mainly for tonsillectomy; viz., glandular dyscrasia and genuine hypertrophy with obstruction.

A third indication, too, is to be accepted, and that is in cases of continuous and prolonged involvement of the cervical glands, pointing unmistakably to the presence of infection in the tonsils which those structures seem incapable of overcoming or throwing off.

Here, also, we must differentiate between cervical glands of long-continued involvement and the cervical glands acutely enlarged and swollen only as a part of a temporary reaction against an acute infection in the throat, after the subsidence of which they rapidly recede to their normal or near-normal state. Both the tonsils and the cervical glands under such circumstances are but playing their normal part in such reaction, and certainly should not be condemned. They have participated in a good fight, have been on the winning side, and after recuperation and replenishment are thoroughly capable of participating in the many fights to come.

In the first group (namely, infants and near-infants) tonsillectomy in recent years in America has come to be a procedure of breadth and extent never practiced by men of the nose-and-throat specialty when this work was almost entirely limited to their field. During that time and, in fact, even today tonsil and adenoid surgery in infants and near-infants, universally speaking, is frowned upon by our specialty.

So far as I am familiar with the work of nose-and-throat men locally and abroad, adenectomy in persistent middle-ear cases is about the extent of the occasional surgery done in these little people, and is about all that has any real justification.

Of all the indications for tonsillectomy enumerated above (viz., real hypertrophy, secretory dyscrasia, chronic local disease, or foc infection leading to systemic poisoning) not o is the rule in infants. Nor is the tempora swelling of defensive reaction in the tonsils mo or less than a very laudable and beneficial r action in the presence of infection.

Some of the most severe anginas that we se with profound systemic toxemia, are in the tonsillectomized throats, where Nature has bee robbed of her defense.

So far in the discussion of this subject ad nectomy has not been considered, although, fact, it alone, without tonsillectomy, is usual about all that is justified in infants, and th practically only for the purpose of clearing persistent middle-ear infection.

Many men, even in our specialty, seem undi posed to think of adenectomy except in conne tion with tonsillectomy, and for no other goo reason than custom and habit. If adenectomy children, especially in infants, is alone indicate then poor surgical balance, surely, is shown doing more.

It is not the purpose of this paper to cov the entire subject of tonsillectomy and methods, but to arouse consideration and discu sion of a matter which I think is soon to bri us embarrassment and chagrin, and which is ready of uncomplimentary note in popular pu lications.*

I have felt for years, and I know that mo of my confreres in this specialty have had t same thought, that tonsillectomy in children pa infancy has been tremendously overdone, a that it not only has been of no benefit but h been distinctly disadvantageous to a large pr portion of this group. And, further, that tons lectomy in infants, so much on the increase du ing the past few years, has seldom been justifie that it has, generally speaking, been distinctly a entirely wrong, and that we should put oursel on record against it in no uncertain terms.

In this widespread, ill-advised surgical activi it should be a matter of satisfaction that we, a specialty, are not responsible for its inaugu tion, and are not now contributing toward continuance or increase.

A SUMMARY OF THE INDICATIONS, TECHNIC AND RESULTS TO BE EXPECTED IN THE USE OF BOTH ARTIFICIAL AND NATURAL HELIOTHERAPY*

Ernest S. Mariette, M.D., F.A.C.P.
Oak Terrace, Minnesota

HELIOTHERAPY occupies such an important place in the treatment of tuberculo- s that a summary of its present status seems arranted. This summary is being prepared as art of a report of a committee of the American anatorium Association on the value of modern berculosis therapy. For more detailed informa- on its readers are referred to the bibliography.

HISTORY

The earliest medical writings contain many eferences to the use of light in the treatment of isease. The Greeks and Romans constructed olaria in their homes and the Egyptians fre- uented sandy beaches. This was probably due the sense of well-being which followed the unbath rather than to the appreciation of any pecific therapeutic properties of light. Oribasius ttempted to popularize light in about the 5th entury A. D., and McCollum and Simonds[1] laim that there is evidence of the use of artificial ources of light at about that time. With the ex- eption of an occasional disciple such as Avicen- ia, whose method formed the basis of our echnic, Henry de Moville, Gaddesden and aracelsus, light therapy appears to have been orgotten until the latter part of the 18th Cen- ury, when it was revived by the French, for use n the treatment of arthritis, tuberculous peri- onitis and Potts' disease. About 1840 Ollier and oncet and Bonnet reported good results in the reatment of arthritis and recommended general ody radiations. The first use of sunlight in a anatorium is credited to Richli, who, although e was not a physician, reported surprisingly ood results in 1885 on patients treated at eldes. Finsen, who was the first to study light cientifically, reported his results in the treat- nent of lupus in 1890. In 1902, Bernhard of St. Moritz, impressed by the success of the local utchers in "curing" their meats in sunlight, ex- osed suppurating wounds to its rays. His re- ults were so successful that he extended its use to cases of surgical tuberculosis using general body radiations. In 1903, Rollier began his now famous work at Leysin. It is due to the efforts of these two men that heliotherapy has become so popular. Their followers, among whom we are to be included, use solar therapy by increasing graduated exposures of the body to sunlight in air. Prior, Hyde and LoGrasso have so popularized heliotherapy in this country that all of the more recently constructed sanatoria contain provisions for its use.

The pioneers in artificial light therapy were Finsen and his followers, Reyn and Ernst. Finsen employed local radiation while Reyn and Ernst advocated general body radiation. In England Sir Henry Gauvain employs natural sunlight and seabathing and utilizes the carbon arc and the quartz mercury vapor lamp and the other sources of artificial light.

PHYSICAL CHARACTERISTICS OF LIGHT

Before proceeding with the indications and technic and results to be expected from both natural and artificial heliotherapy, I believe a brief discussion of the physical characteristics of the various sources of light, as well as their physiological effects, is warranted.

Light has been defined as an electro-magnetic disturbance of the ether. These disturbances travel through the ether in wave form at a rate of 186,300 miles per second and their frequency varies inversely as the length of the wave. The unit of measurements of the shorter wave is the angstrom unit, 1/10,000,000 of a mm., while in the infra-red region the unit is the micron, 1/1000 of a mm., and in the radio wave lengths it is the meter. When the disturbances or radiations are arranged according to the wave lengths, they present a definite spectrum (Fig. 1). At one end are the cosmic rays, so short and of such a high frequency that no one has yet been able to define their limits. At the other end of the spectrum are the long radio waves. According to Luckiesh[2] these measurements constitute

"a locality in the wave length scale without being definitely fenced," so the figures given mark the approximate upper limit of the various zones. In general, the spectrum consists of a visible portion from the violet to the red of wave lengths from about 3,900 to about 7,600 A. U. flanked on either side by an invisible spectrum which begins with the ultraviolets and infra-reds and includes the other rays mentioned. The violets and ultraviolets are the chemically active rays, the reds and infra-reds being the heat producing rays.

Fig. 1. The Electro Magnetic Spectrum. This was compiled from material gathered from various sources. The measurements given represent zones in the spectrum rather than definite limits. The human organism in its struggle for existence has adapted itself to the rays of the sun's spectrum. This is the zone of moderate penetrability. The rays on either side of the sun's spectrum become increasingly penetrating as they increase or decrease respectively. The shorter rays such as the cosmic or Roentgen are more penetrating than the ultraviolet, visible or infra-red.

THE SUN'S RAYS

The sun's spectrum contains rays from about 2,900 A.U. to about 30,000 A.U., the earth's atmosphere filtering out the others. Therefore, any benefit to be derived from solar radiation must be derived from rays within those limits. From 1 to 5 per cent of the total output of the energy of sunlight is in the ultraviolet rays[3], that is, in the region from about 2,900 A.U. to about 3,900 A.U., the beginning of the visible rays. This variation depends not only upon the time of day and the season of the year, but also upon the latitude and the altitude and the condition of the atmosphere, that is, whether it is clear or filled with moisture, dust or soot. Thus it is obvious that all localities in the United States do not have the same intensity of sunlight. Greider and Downes[4] have considered the spectral energy curve of noon sunshine in summer and winter for Colorado Springs as representative of mountain sunshine, and East Akron, Ohio, as representative of low altitude sunshine (Fig. 2). The average of these four curves is called "Clinical sunshine" or "fall sunshine." It has been suggested that this average be used as a standard for comparison with artificial light.

According to Fabry, as reported by Coblentz[5] and others, the intensity at 2,900 A.U. is only 1/1,000,000 of that at 3,150 A.U. and only 1/40,000,000 of that of the visible spectrum. Coblentz claims that on the clearest day at noon hour in summer in Washington, D. C., the amount of ultraviolet solar radiation useful for preventing rickets (of wave lengths less than 3,100 A. U.) amounts to less than 0.3 per cent of the total incidence solar rays, which decreases to an imperceptible value at sunrise or during cloudy weather[6]. Thus the amount of ultraviolet rays in the sun's spectrum is relatively small. This fact should be considered when selecting the artificial light to be used as a substitute for sunlight.

Diffuse sunlight is particularly intense at the seacoast and diminishes with increased altitudes. When the sky is covered with clouds and the sun is hidden, diffuse sunlight may still be rich in actinic rays and useful for sun treatment. Between 10 A. M. and 2 P. M. the intensity of sunlight is maximal. It is at this time of day that the various short wave lengths are most abundant but the high temperature at these hours may be ntolerable for sun cure[7].

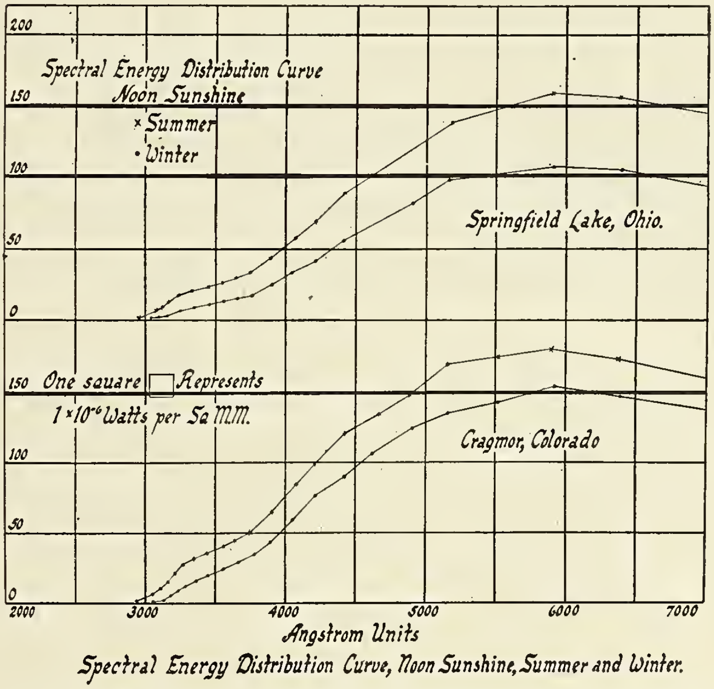

Fig. 2. Spectral energy distribution for mountain and lowland sunshine. Greider and Downes.

The ultraviolet rays are reflected by sand, snow and water, while water and water vapor absorb the infra-red rays above 14,000 A. U. thus increasing the relative intensity of the ultraviolet rays. Fog, however, will absorb the ultraviolet. Thus the best localities for heliotherapy are the seacoast, when free from fog, the desert and the mountains where the atmosphere is clear.

THE MERCURY ARC LAMP

There are three types of mercury arc lamps now in general use as artificial sources of light. Two of these use a quartz burner which trans-

mits rays down to about 1,850 A.U., and one of these has a special glass bulb or burner which absorbs the rays of less than about 2,800 A.U.

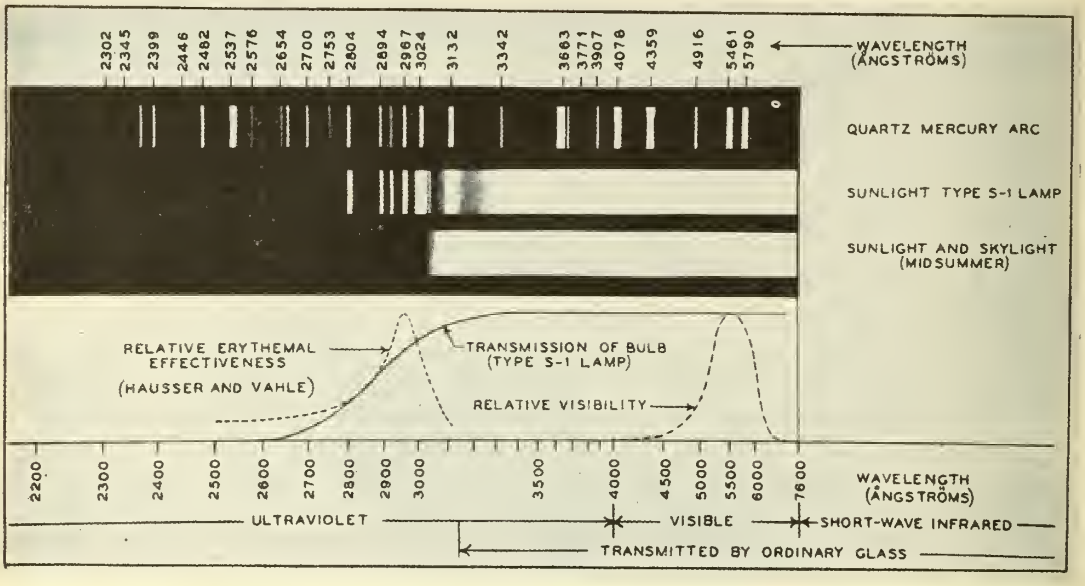

Fig. 3. Spectrum of S-1 lamp compared with that of a quartz mercury arc and sunlight as prepared by Luckiesh.

The difference between the two types of lamps using a quartz burner is, that in one, both electrodes are of mercury, while in the other, one electrode is of mercury and the other of tungsten. Both of these lamps are made in an air-cooled type for general body treatment and a water-cooled type for local radiation. Their spectrums begins at about 1,850 A.U. with a high proportion of ultraviolet to the total output. According to Coblentz[5], about 20 per cent of the total radiations are of wave lengths less than those found in natural sunlight (2,900 A.U.). As about[3] two-thirds of all the wave lengths less than 14,000 A.U. are of radiations below about 4,500 A.U., these lamps emit very little infrareds except from the heated quartz, the electrodes, the supports and the hood. In the tungsten anode type of lamp, some additional infrared radiations are obtained from this anode. When these two types of lamps are operated on the same energy input, there is very little difference in their ultraviolet output[8,9]. The short ultraviolets below 2,900 A.U. are very irritating but they have strong germicidal properties and should be of great value in treating superficial wounds. "Physically, there is no comparison between this type of radiation and that of the sun and it is hardly to be expected that these two sources of light will give the same results in all types of treatment."[8,9]

The more recently constructed quartz mercury lamps do not age as rapidly as those constructed several years ago.[9] Of the two types of lamps, the one with the tungsten and mercury electrodes seems to age slower than does the lamp with both electrodes of mercury.

Because clear distilled water does not in any degree absorb ultraviolet rays, Kromayer developed a water-cooled quartz mercury vapor lamp which is used very effectively for local applications.

The mercury arc lamp, S-1, with two tungsten electrodes is a combination of a mercury arc between highly incandescent electrodes of tungsten.[10] There is also a tungsten filament which operates in parallel with the mercury arc but at a considerably lower temperature than the electrodes. In this combination the ultraviolet rays from the mercury are supplemented with visible and infra-red rays from the tungsten, thus reducing the proportion of the ultraviolet in relation to the total output as compared with the two types of quartz mercury lamps discussed above. This lamp also uses a special glass bulb which absorbs the rays shorter than about 2800 A.U. and in that particular as well as in the greater proportion of infra-red it is more closely allied to the sun's spectrum. According to Coblentz,[10] the total intensity at a distance of three feet from the lamp, without the wire mesh cover, is about one-tenth to one-twelfth that of average solar radiation, and about 1.5 per cent of the radiations are of wave lengths of less than 3,130 A.U. The bulb blackens, however, with use due to a deposit on the inside and according to the manufacturers, should be replaced after 300 to 400 hours. Some bulbs, however, have had to be replaced after fifty to one hundred hours. The manufacturer has done this in some cases without any charge. Physically, the spectrum of this lamp is more closely allied to that of the sun than the spectrum from the other types of mercury arc lamps (Fig. 3). Therefore, it should give results more comparable to those obtained from the use of natural sunlight.

THE CARBON ARC

The carbon arc is the hottest source of artificial radiation readily obtainable and in this respect it is the closest approach to sunlight.[10] The radiation emitted from the carbon arc depends upon: the size of the electrodes and the metals with which the carbons are impregnated; the direction of the current when direct current is used; and the amount of electricity consumed. The white flame carbon emits relatively few ultraviolet rays of wave lengths shorter than about 2,200 A.U. It emits relatively more of ultraviolet from about 2,900 A.U. to about 3,100 A.U. than does the sun's rays. Also at about 3,890 A.U. it is relatively more intense than sunlight. In the visible portion of the spectrum, however, the sun's rays are more intense. The arc is strong in infra-red radiations of wave lengths longer than about 30,000 A.U. which the atmostphere has filtered out of the sun's rays.

When the carbon arc is covered with a Corex-D chimney which filters out the ultraviolet rays shorter than about 2,900 A.U. and infra-red rays longer than about 40,000 A.U., the white flame carbon emits a light which is the closest approach to natural sunlight we have.[10] Therefore, the results obtained in this type of artificial light should be more comparable to those obtained in natural sunlight, than from any other artificial source of light.

The manufacturer claims that the 60 ampere Eveready Carbon Arc Lamp with a white flame carbon and at proper distance (4 to 6 feet) from the patient will produce from 1 to 1.5 times the amount of ultraviolet rays of 2,900 to 3,100 A.U. present in "clinical sunlight." At a distance of six feet from this arc the total intensity of radiation is about one-fifth that of clinical sunlight and about one-sixth of one per cent of this radiation is of wave lengths shorter than 3,100 A.U.[11] By varying the distance of the carbon arc lamp from the patient, an intensity approximating "clinical" or "fall" sunshine may be obtained (Fig 4). If brought close enough to the patient, the carbon arc of low amperage may prove as effective as carbon arcs of higher amperage operating at a greater distance. The operating distance* for a patient undergoing treatment is a matter of trial and depends upon the results desired and the manner of radiation and cannot be determined by radiometric measurements.[5]

PHYSIOLOGICAL EFFECTS OF LIGHT

According to the law of Grothus formulated in 1819, light rays must be absorbed in order to be utilized by the body. As the ability of the body to absorb the rays varies with their wave lengths, it is obvious that their physiological effects vary also. The red and near infra-red rays, or the heat producing rays, have the greatest penetrating power. Their physiological effect is the effect of heat such as the production of a hyperemia and a pigmentation and the well known effects of heat on chemical reactions. The visible rays produce heat, light and metabolic changes. The ability of the violet and ultraviolet rays to penetrate the skin decreases as their wave lengths decrease, but the shorter the wave lengths the more readily are they absorbed by the skin. The heat rays through the production of a hyperemia enhance the effect of the vital rays, which is that of a chemical agent.

THE ACTION OF THE SKIN

The red and infra-red rays below 14,000 A.U. penetrate the skin and produce an immediate erythema which fades rapidly.[3] Those above 14,000 A.U. do not penetrate the skin, but if too intense may cause blistering. There is also a delayed erythema which does not appear for two or more hours. This is due to the shorter ultraviolet rays and may in all probability be a secondary reaction resulting from tissue injury, which, if it has been carried too far, may be accompanied by edema.

---

*Those interested in the spectrums of the different carbons, which vary from that of the white flame carbon to one as rich in ultraviolets as that obtained from the mercury arc lamp, can obtain such information either from the National Carbon Company or from the Bureau of Standards, through the publications of Coblentz, a fairly complete bibliography of which is published in his article in the Journal of American Medical Association for June 1, 1929, V. 92: 1834-1837.

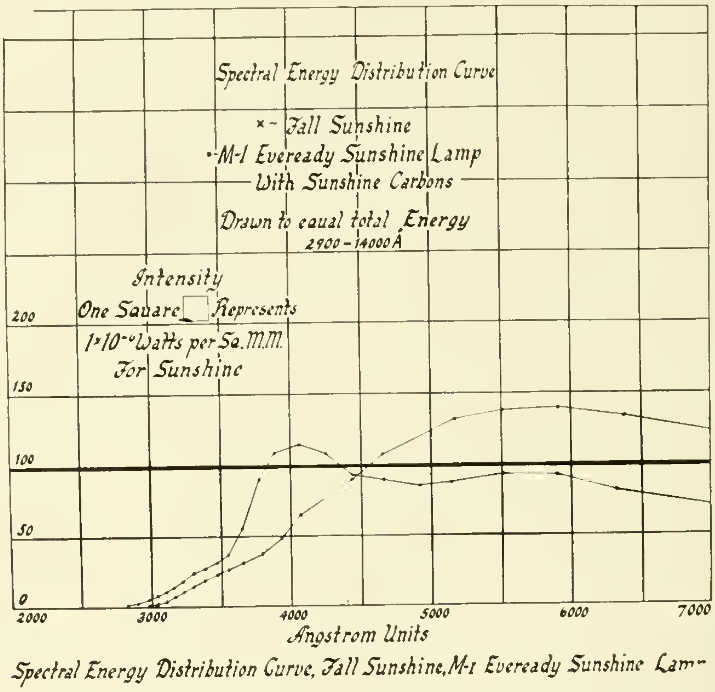

Fig. 4. Spectral energy distribution of "clinical sunshine" compared with that of an Everready carbon arc lamp as prepared by Greider and Downes.[4] It is claimed that while the relative amount of rays from about 2,900 to about 3,100 is some greater for the carbon arc lamp, than at 1 meter the absolute amount of this energy is essentialy equal to that in clinical sunshine.

Some claim that nature protects itself against this phenomenon through the formation of pigment or a tanning due to the deposit of melanin in the lower layers of the epidermis. Miescher[12] believes that the increase in the thickness of the stratum corneum, which occurs as a result of light is nature's protective mechanism. The type of pigment varies with the type of radiation used. That from the mercury arc utilizing the shorter radiations is yellowish brown and is not as permanent as that obtained from the rays of longer wave lengths such as the S-1 mercur arc lamp or the carbon arc or the sunlight. Th pigment from these latter sources is reddish o blackish-brown, depending upon the degree o the pigmentation. The exact effect and purpos of this phenomenon is not clearly understood. I

M-1 Eveready Sunshine Lamp	0.16	42.5	57.3		1080

addition to protecting the body against over-doses of ultraviolet rays, it may sensitize the skin so that more of the visible rays are absorbed. The rays between about 2,900 and about 3,200 A.U. produce an erythema and a dilatation of the capillaries, accompanied by a rich brown pigment. Uhlman[13] believes while the same wave length can produce both pigmentation and hyperemia hat pigmentation can be produced independently of hypermia, i.e., by radiation of a different wave ength than those which produce hyperemia. In pite of this the clinician must not ignore hyperemia in determining the effect of pigmentation. Rollier[14] and his followers believe that pigmentaion has a great deal to do with the success of the reatment and can be taken as an indication of extent of the healing. We have found in over nine years of experience with heliotherapy that he patients who are well tanned have generally made the most improvement. However, it is well known that patients who have failed to tan have occasionally recovered while those who have developed marked pigmentation have occasionally ailed to heal. Luckiesh[15] claims that tanning hould be taken as an indication of outdoor life ather than as a measure of health, and conversey that pallor is an indication of indoor life ather than of illness.

The normal physiological function of the skin eems to be increased in light therapy. Following n erythema dose of light there is a transitory ncreased resistance to staphlococcus, pneumococus and streptococcus infections. After pigmenation occurs this increased resistance to infecion is more permanent. Recent work by Eidinow nd Hill indicates that other wave lengths than he anti-rachitic ultraviolet may also play an important part in this phenomenon.[16] Tanned skin s soft and velvety and presents a marked conrast to the toneless, flabby, cold skin of the pale ndividual. The value of light therapy is inreased when it is supplemented by the tonic efect of moving air, which acts directly upon the asomotor system causing an alternate dilatation nd contraction of the skin capillaries. Under uch conditions there is an increase in the metaolic rate and mineral metabolism. There is a marked increase in muscular tone which acompanies the use of light therapy and may be in part due to this massaging effect of the moving air.

Cholesterol, which is found in large quantities in the skin, contains ergosterol as an impurity. This is activated chemically by the ultraviolet rays resulting in the formation of vitamin D. Thus part of the beneficial effects of light therapy is to be found in the results which are characteristic of vitamin D. The shorter ultraviolet rays from about 2,200 to about 2,700 A.U., which occur in artificial sources of light, possess great bactericidal properties but they are very irritating and destructive of protoplasm. It is possible also that the products resulting from such destruction may be harmful and that these shorter rays may therefore partially neutralize the effects of the longer rays, (about 2,700 to 3,100 A.U.). Therefore, Coblentz and Starr,[16] quoting Heilbron, Kamm and Morton, and Bills, Honeywell, and Cox, believe that the destructive properties of these short rays is great enough to destroy vitamin D, and so recommend that screens which filter out the ultraviolet rays below about 2,900 A.U. be used with all artificial sources of light. More recently Marshall and Knudson[17] have studied the formation of vitamin D at wave lengths of 2,536 A.U. and 2,800 A.U. They conclude that the formation of vitamin D is in direct proportion to the light quanta absorbed and is independent of the wave length. Therefore, if the time of exposure is so adjusted that the amount of light absorbed at the various wave lengths is the same, the same amount of vitamin D is formed. In any event, the period of treatment with the artificial sources of light containing these short rays is measured in seconds and minutes rather than in minutes and hours as is the treatment with sunlight.

THE PHYSIOLOGICAL EFFECT UPON THE BLOOD STREAM

The action of the reds and infra-reds below 14,000 A.U. and the violet and the near ultraviolet rays which penetrate the skin and are absorbed by the blood stream, is very complex. It is thought to be in part a photochemical[9] reaction which manifests itself locally and also on distant tissues and organs and for some time after radiation has ceased. When the light treatment is carried too far, its action is destructive rather than stimulative. The heat rays may increase the alkalinity of the blood and can raise the temperature of the blood 3° C. without disturbing bodily temperature. The calcium content of the blood is also increased due probably to the ultraviolet rays.

Basal metabolism is increased under light therapy, but the increase may be due mainly to the moving air. Due to the increased activity of the skin, elimination is increased, resulting in a reduction of blood urea nitrogen and an improvement in nutrition. There is a slight transitory lowering of blood pressure. The pulse rate shows an initial rise which subsequently drops to normal or below unless the treatment has been too prolonged. There is also an immediate rise in bodily temperature which drops to within one degree of normal or to normal shortly after the radiation has ceased.

INDICATIONS FOR HELIOTHERAPY

Light therapy is a popular but potent therapeutic agent which, unless carefully supervised, will do untold harm. It should not be considered as a cure-all nor is it nearly as effective when used alone as when combined with other accepted forms of treatment. In the words of Edgar Mayer[3], "to believe that sunlight or artificial sources of light will cure all forms of surgical tuberculosis, to be unduly optimistic about this treatment and to consider it a specific form of treatment, to use it without sound medical guidance and adequate equipment and finally to employ it to the exclusion of rest and hygenic regimen, eliminating orthopedic measures or the occasional necessary surgical intervention in bone and joint tuberculosis, is bound eventually to dishearten many sufferers and to bring discredit on an otherwise desirable method of treatment."

Whether artificial or natural light is indicated, will depend upon the season of the year, the condition of the atmosphere, the sources of light available as well as the type of lesion to be treated and the condition of the patient.

SEASON OF THE YEAR

In the temperate zone general solar radiation is indicated during the summer whenever it is available. Because climatic conditions make this impractical in winter and because window glass transmits only 1 to 2 per cent of the available rays at 3130 A.U., the advisability of using special window glass for indoor radiations is raised. As the winter sun is poor in ultraviolet rays, it is obvious that if such a glass is to have any value its transparency should be high. Therefore, in 1928, Coblentz[18] recommended that after complete solarization such glasses should transmit at least 25 per cent of the available rays at 3020 A.U. Due to more recent investigations[19] he now believes that a transmission of "45 to 50 per cent would be more nearly in agreement with physiological observations" and recommends that the minimum specifications of such glasses be raised to 35 per cent transparency at 3020 A.U. He adds very succinctly that when such a glass is needed the best is none too good and that one cannot afford to run the risk of using a glass of doubtful effectiveness. Dust may reduce the transmissibility of these glasses by 30 to 40 per cent.

Coblentz' and Starr's recent report[6] on the transmissibility of the various glasses marked prior to February 1, 1929, is very enlightening. They conclude that in thicknesses of 2.3 mm. these glasses may, after complete solarization, be divided into six groups according to their transmissive properties at 3020 A.U., as follows:

(a) Common window glass and quartzlite less than 1 per cent.

(b) Vitaglass, Sanalux and Renovic, about 25 per cent.

(c) Holviglass, Sunlit and Sendlinger's ultraviolet glass 35 to 40 per cent.

(d) Helioglass, Uviol-Jena, and Neuglas, 45 to 50 per cent.

(e) Corex-D glass 60 to 65 per cent.

(f) Corex-G981FF[2] and Quartz glass 80 to 90 per cent.

Because of the decrease in intensity in the ultraviolet rays in the wave lengths from about 2900 to about 3050 during the winter time, one cannot but wonder whether better results would not be obtained from artificial sources of light during these months than from the sun as it is transmitted through these special glasses.

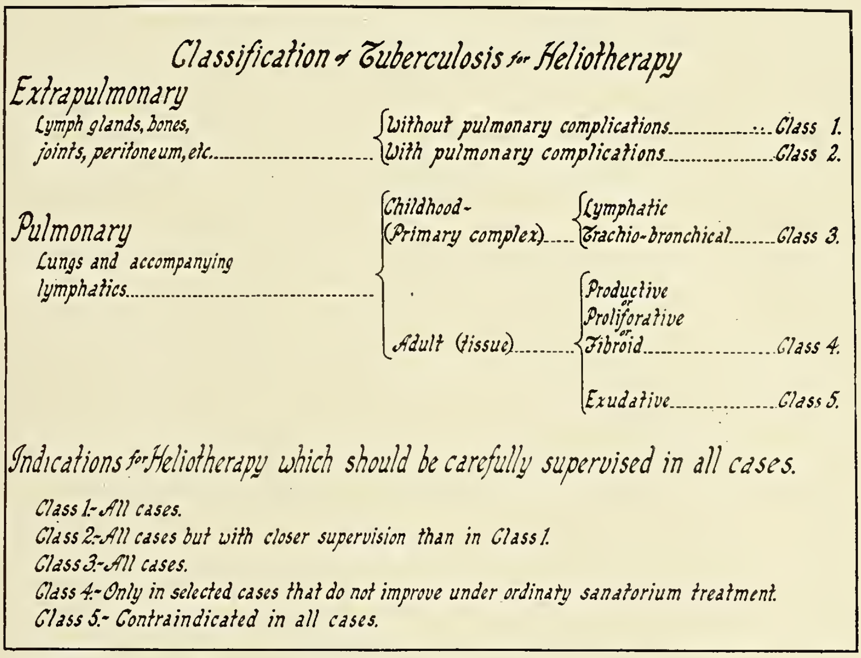
CONDITION OF THE ATMOSPHERE

Clear atmosphere transmits ultra-violet rays well, but fog, dust, and smoke interfere tremendously with their transmission. In general, more of the ultraviolet rays are available throughout a greater portion of the year in the tropics than they are anywhere else. In spite of this, due to atmosphere conditions Manila has a lower percentage (51) of the theoretical sunshine than Chicago (57) or New York (56) while Denver or Santa Fe has a still larger percentage (69 and

76 respectively).[7] This relationship varies, of course, with the season and with the year.

AVAILABLE SOURCES OF LIGHT

When sunlight is not available, some sort of artificial light is indicated. Because the spectrum of the quartz mercury arc differs so markedly from that of the sun, it is not the source of choice as a substitute for general sunlight irradiations. This type of artificial light should be reserved for those conditions where ultraviolet rays without heat are desired and for special conditions, such as superficial areas of tuberculosis or intestinal tuberculosis. The water cooled quartz light is indicated for local suppurating tuberculosis, draining sinuses, tuberculous otitis media, tuberculous laryngitis and allied conditions. As the spectrum of the S-1 lamp more closely approximates that of sunlight, it should have a wider range of usefulness than the quartz mercury arc. However, the bulb blackens with use and has to be replaced frequently. The spectrum of the carbon arc lamp with the corex-D filter and the white flame carbon, more closely resembles that of natural sunlight than that of any other artificial source of light. Moreover, it is always of the same intensity and does not deteriorate with use. Therefore, it is the artificial light of choice as a substitute for natural sunlight. When this source of light is used with a suitable fan to secure the proper circulation of air, the following criticism of Mayer's[20] concerning irradiation with artificial light loses much of its force: "Irradiations with artificial light as ordinarily employed indoors lacks some apparently important accompaniment of outdoor solar exposure, such as constantly moving fresh air with its affect produced through the skin and respiration and the uniform warming of the whole cutaneous surface with its production of a sense of stimulation followed by comfort, well-being and relaxation."



Classification of Tuberculosis for Heliotherapy
Extrapulmonary
Lymph glands, bones, joints, peritoneum, etc.
Without pulmonary complications ... Class 1.
With pulmonary complications ... Class 2.
Pulmonary
Lungs and accompanying lymphatics
Childhood- (Primary complex)
Lymphatic
Trachio-bronchial ... Class 3.
Adult (Tissue)
Productive or Proliforative or Fibroid ... Class 4.
Exudative ... Class 5.

Indications for Heliotherapy which should be carefully supervised in all cases.

Class 1:- All cases.
Class 2:- All cases but with closer supervision than in Class 1.
Class 3:- All cases.
Class 4:- Only in selected cases that do not improve under ordinary sanatorium treatment.
Class 5:- Contraindicated in all cases.

Fig. 5. Slight Modification of Watson's Classification. If the general rules of this classification are followed, much sorrow and many disappointments will be avoided.

TYPE OF LESION AND CONDITION OF PATIENT

The type of lesion and the condition of the patient will be discussed together. Figure 5 represents a slight modification of an outline of the indications for heliotherapy according to the type of tuberculosis as prepared by Watson. If the general rules of the outline are followed much harm and many disappointments will be avoided. Classes 1 and 2 include tuberculosis of the skin, the superficial glands, the bones and joints, the genito-urinary tract, the peritoneum, the intestinal tract, the middle ear, the larynx, the eyes, as well as the anus and the lower rectum. In outlining the indications for heliotherapy in extra-pulmonary tuberculosis, these two groups will be considered together as the pulmonary focus generally improves with the improvement in the extra-pulmonary lesion. Therefore, a pulmonary complication is an indication for closer supervision rather than a contraindication.

General body radiations in the sunlight in accordance with Rollier's schedule is indicated in all of these cases except the acute progressive type. This should be supplemented in the presence of ulcers, draining sinuses or fistulæ by the use of Thezac Porsmeur lens. This is a biconvex lens with a diameter of 12 inches and a focal point of 72 inches.[21]

When sunlight is not available, artificial light should be used. In certain instances, local applications of light from artificial sources are indicated in addition to general solar radiations.

Tuberculosis of the skin in this country does not present the same problem that it does in Europe. It is usually a local manifestation of a systemic disease and responds very well to heliotherapy. The artificial sources of light emitting rays of short radiations may be of special value in this particular type of tuberculosis.

In tuberculosis of the superficial lymph nodes, general body radiations in sunlight plus local X-ray treatments are indicated in all cases, even where softening and sinus formation is present. When sunlight is not available, artificial light is indicated.

Heliotherapy, combined with good orthopedic treatment, including orthopedic appliances and the judicious use of surgery in adults is indicated in bone and joint tuberculosis. Rollier reports excellent results in bone and joint tuberculosis with heliotherapy and the use of orthopedic appliances but without surgical intervention except in rare instances. His results, I believe, are due to a meticulous attention to the details of the treatment and to the fact that heliotherapy can be carried out over a longer period of the year at Leysin than it can in Minnesota. Petter believes[22] that such conservative treatment, that is, heliotherapy plus orthopedic appliances but without surgery should be limited to the early cases of joint tuberculosis where there has been no destruction of bone and no erosion of cartilage. In such cases, a functioning joint may be secured. When bone destruction has occurred, the time required for "a cure" with heliotherapy is greatly increased, and the possibility of a relapse in the case of a functioning joint is greater than with an ankylosed one. Both of these factors, that is, the length of treatment and the possibility of relapses are of prime importance to the patient and to the community which is supporting him during his period of convalescence. Hence, surgery, which will shorten the period of treatment and reduce the possibility of relapse through the production of an ankylosed joint, is indicated at the proper time. This, in most instances, is not as soon as a diagnosis is made, but is only after the process has become quiescent under the use of bed rest, orthopedic appliances and heliotherapy. In such instances surgery is not considered a cure-all, but rather a permanent splint which, by increasing the rest of the diseased part, protects and enhances the healing already secured. Postoperative convalescence can be materially reduced through the use of heliotherapy. Heliotherapy is valuable in the treatment of sinus and abscess formations.

In children, heliotherapy plus rest and good orthopedic sense will produce astonishing results. Surgery is to be used only as a last resort because it is so likely to interfere with the growth of the child.

In genito-urinary tuberculosis general solar therapy with artificial light therapy as a substitute is indicated, either as a curative, palliative or postoperative measure. As renal tuberculosis is considered to be a blood-borne metastatic infection, it would seem that it must be bilateral at first.[23]. In unilateral renal tuberculosis, then, the process must have healed in one kidney while it progressed in the other. Thomas and Kinsella, as a result of a study of genito-urinary tuberculosis carried on at Glen Lake Sanatorium over a period of years, believe that early renal tuberculosis heals. This is in accordance with the conclusions of Medlar[26] as a result of a study of 100,000 microscopic sections of the kidney. In such cases, heliotherapy combined with rest and other factors of sanatorium regimen is the treatment of choice; however, when unilateral renal tuberculosis has gone far enough to produce an ulceration into the kidney pelvis which can be demonstrated on a pyelogram, or to definitely impair the function of the kidney, a nephrectomy is indicated.[24, 25] In such cases heliotherapy is indicated to prepare the patient for the operation and is the postoperative treatment of choice. In bilateral renal tuberculosis, surgery is contraindicated except in certain selected cases when it is to be used as a palliative measure. In such cases heliotherapy is indicated, and in many instances excellent clinical results are reported, including even the disappearance of tubercle bacilli from the urine. It is rather commonly believed, however, that sooner or later these lesions will relapse.

Genital tuberculosis is usually secondary to a renal infection, although occasionally it is apparently a blood-borne infection from some other focus than the kidney. Therefore, in all cases of genital tuberculosis a thorough search should be made for a renal focus, and when found, this should be removed. Heliotherapy is indicated in all cases of epididymitis and in the early cases, may be sufficient to produce a cure. When it does not, an epididymectomy is indicated. With the urinary focus removed and the external evidence of genital tuberculosis properly treated, the lesion in the bladder, the prostate or seminal vesicle usually heals promptly under heliotherapy.

Sunlight therapy combined with local applications of artificial light is indicated in tuberculosis of the intestinal tract. Here the influence of light upon the absorption of calcium from the intestinal tract seems to have a direct bearing upon the cure of the intestinal tuberculosis.

Tuberculosis of the peritoneum is usually a secondary manifestation of a tuberculous lesion in the abdominal cavity. General solar irradiation with artificial light therapy as a substitute is indicated in this type of tuberculosis. Under such treatment there is often a marked reduction in symptoms and local signs resulting in a clinical cure. When the original focus happens to be a fallopian tube or an appendix there is much less possibility of a future relapse if these organs are removed than if they are not. So in certain conditions, heliotherapy should be supplemented by surgery.

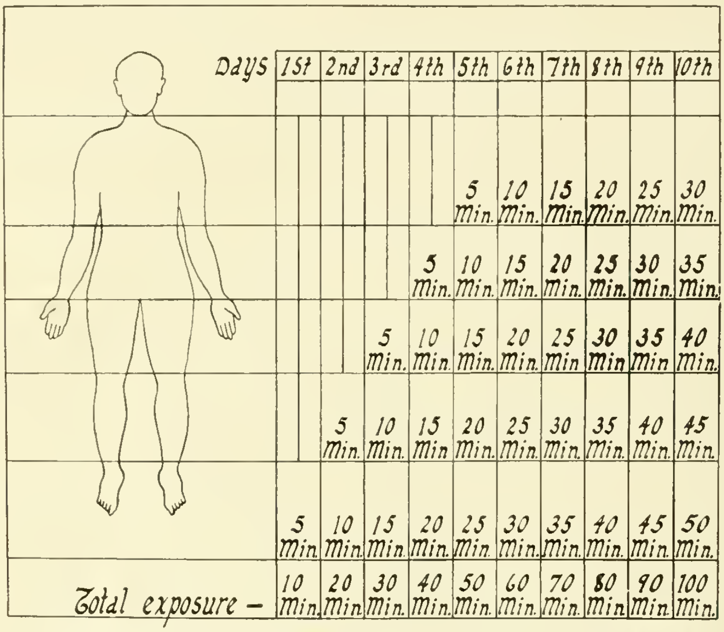
General body radiations of natural sunlight are indicated in tuberculosis of the ear, the eyes, the larynx, as well as ulcerations of the anus and lower rectum, supplemented, except in tuberculosis of the eye, by local application of the water-cooled quartz mercury vapor lamp. Heliotherapy under such conditions, combined with the other forms of sanatorium treatment, including surgery in connection with ulceration of the anus and perirectal abscess and fistula in ano, gives excellent therapeutic results.[27, 28]

In Class 3, general solar radiations supplemented by artificial light for use in cloudy weather and when natural sunlight is not available give excellent clinical results. Because the acute phase of this particular type of tuberculosis usually clears up rather promptly, nothing is to be gained in the use of heliotherapy until it has quieted down. Heliotherapy properly carried out will give the child the maximum assurance against further disability from tuberculous disease.

Class 4. LoGrasso[29] believes that even cases of adult tuberculosis with moderate fever are suitable for heliotherapy. In our experience it would seem better to postpone heliotherapy in such cases until strict bed rest over a prolonged period of time has failed to produce the desired results. Many patients who cannot tolerate natural heliotherapy in the beginning, can do so after a course of artificial light therapy.

When there is no fever present, general body radiation in the sunlight, either supplemented by or preceded by radiations from artificial light is indicated in selected cases. When such cases are properly selected and heliotherapy properly supervised, hemoptysis, miliary tuberculosis and pulmonary spreads are not encountered any more often than under ordinary sanatorium treatment. When a special therapeutic agent is used and spreads are encountered, one is apt to attribute the spread to the therapeutic agent and forget that tuberculosis is a relapsing disease and that there will be a certain proportion of relapses no matter what type of treatment is used. In general, the most suitable cases for heliotherapy in Class 4 are those which have become stationary under the ordinary forms of sanatorium treatment and which still have a fairly large amount of tuberculous pathology. The aim of heliotherapy in such cases is, of course, to clear up as much of the pathological picture as possible in order to reduce the possibility of future relapses. I can see no indication for heliotherapy in Class 4 when the patient is progressing satisfactorily under the ordinary forms of sanatorium treatment.

Tuberculous pleurisy with effusion, while it is usually due to an underlying pulmonary focus, often clears with the aid of heliotherapy. Therefore, every case of tuberculous pleurisy with effusion, unless accompanied by the exudative type of tuberculosis, should have heliotherapy. This measure is very effective in the prevention and even in the treatment of a tuberculous empyema.



Days	1st	2nd	3rd	4th	5th	6th	7th	8th	9th	10th
					5 Min.	10 Min.	15 Min.	20 Min.	25 Min.	30 Min.
				5 Min.	10 Min.	15 Min.	20 Min.	25 Min.	30 Min.	35 Min.
			5 Min.	10 Min	15 Min.	20 Min.	25 Min	30 Min	35 Min	40 Min.
		5 Min.	10 Min.	15 Min	20 Min.	25 Min.	30 Min.	35 Min.	40 Min.	45 Min.
	5 Min	10 Min.	15 Min.	20 Min.	25 Min.	30 Min.	35 Min.	40 Min.	45 Min.	50 Min.
Total exposure –	10 Min.	20 Min.	30 Min.	40 Min.	50 Min.	60 Min.	70 Min.	80 Min.	90 Min.	100 Min.

From the 10th to the 15th day, increase according to same scale. From the 15th day, all the previously exposed portions of the body should receive the same amount of insolation as the longest exposed part,—increasing the time 5 minutes daily, till a bath of from 3 to 4 hours is taken.

Fig. 6. Rollier's Schedule of Sun Dose. This is not a hard and fast schedule but it is the standard upon which individualization is based. The "total exposure" means total for each exposure front and back and is usually repeated three times a day.

In our opinion, heliotherapy is contraindicated in Group 5. There may be exceptions to this rule in very selected cases, but as a general proposition no one in Class 5 should receive heliotherapy. Many patients who were originally in Class 5 will, under ordinary sanatorium treatment, improve and progress to Class 4. Under such conditions and when the process becomes stationary, heliotherapy may be indicated to increase the extent of the pathological improvement.

TECHNIC

In discussing the general technic of the sun-bath, Rollier[30] states "the importance of carefully dosing the amount of exposure to sunlight permitted to each patient could hardly be overemphasized, as there are few other methods of treatment in which dosage and careful individualization are of greater importance. It would hardly be an exaggeration to say that it is on the initial period, that of acclimatization and adaption, that the eventual success of the treatment depends. The manner in which the patient reacts to sunlight, and following from this the amount of insolation it will be advisable to give him, are the fundamental points in heliotherapy."

Therefore, before heliotherapy is given, each patient must have become acclimated to his new environment and must have been thoroughly studied by the physician. Perhaps in no other field of tuberculosis therapy will undue haste often spoil an otherwise favorable prognosis. In all instances, the heliotherapist must individualize, as it is obvious that one with only a small localized focus of extra-pulmonary tuberculosis and in excellent general health need not be treated in the same manner and degree as a person with several foci and fever, and whose general condition is not so good. Rollier's arbitrary plan of dosage is outlined in Figure 6. The general technic of the sun-bath as advocated by Rollier is given in complete detail in his excellent book, "Heliotherapy,"[31] therefore it will not be repeated in this summary. In brief, his plan is to divide the body into five zones. The time of exposure is gradually increased as well as the zone till the entire body, with the exception of the head, is receiving a total of two to four hours' radiation a day. The maximum amount of radiation will vary with the atmospheric conditions, the individual patient, and the individual therapist. Some physicians advocate a single exposure of from two to four hours a day, while others prefer to have the period of irradiation broken into exposures of fifteen to thirty minutes front and back, followed by a short rest of fifteen to thirty minutes or more. This procedure is repeated as often as is necessary to secure the desired number of minutes exposure for that day.

In planning solar radiations one should bear in mind that the ultra-violet intensity of the sun's rays is greatest from 10 A. M. to 2 P. M., decreasing to an imperceptible value at sunrise and sunset and in cloudy weather. However, the heat of the day may make long exposures during that period inadvisable and then one is forced to choose between giving solar radiations at less desirable times of the day or of decreasing the time of exposure. If other hours of the day are selected, the patient will, at least, receive the benefit of moving air and heat, with the well known effect of this combination upon general body metabolism and function. By combining short periods from both the best time of day and less desirable times, a longer period of solar radiation may be obtained with greater benefit to the patient.

Our maximum exposure for the average patient during the summer of 1930 was two hours per day, either from 10 A. M. to 2 P. M., or one hour in that period and one hour earlier in the morning, depending upon the manner in which the patient reacted to light. The maximum exposure at one time was a half hour front and back, followed by a rest of at least a half hour.

Immediately after an exposure to the sun, there is generally an increase in bodily temperature which, if it is due to the normal physiological effect of heat, will drop to almost normal within a half hour after the treatment has been terminated. If it does not, then the dose of light should be reduced. We have had patients who could only take one minute of solar exposure at the beginning of treatment, but who gradually became acclimated to the sun's rays and could tolerate large doses of heliotherapy and finally progressed favorably. The pulse rate is likewise elevated after radiations but it too should fall to approximately normal within a half hour after exposures have been terminated. Thus the body temperature and pulse reaction plus the general condition of the patient serve as important checks on the progress of the treatment. Therefore, it is necessary that they should have been observed for some time before treatment is commenced in order to determine the individual normal.

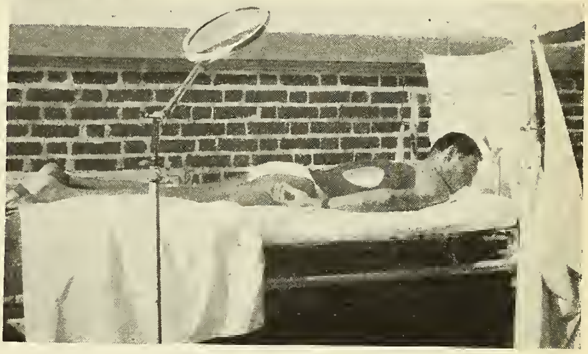


Fig. 7. Thezac Porsmeur lens.

The technic for the use of the Thezac Porsmeur lens in general is as follows: The lens is focused over the site of the lesion so as to obtain a circle of light not less than seven inches in diameter. The treatment is usually started at five minutes and is gradually increased till a maximum of thirty minutes is reached. This may be repeated once during the day if desired.[21] Here also individualization is necessary and the exact size of the circle, the initial period of treatment, the rate of increase and the maximum time of treatment are a matter of trial and judgment. They will vary with the lesion, the condition of the patient and the therapist (Fig. 7).

DOSAGE OF LIGHT

The dosage of light varies with the skin reactions desired. Some heliotherapists prefer an erythema only; others an erythema and a pigmentation. Rollier[32] believes that a fairly close parallelism exists between pigmentation and a favorable prognosis. We prefer a ruddy erythema with a tan bordering on a mahogany rather than a chocolate brown. Eidinow and Hill, as reported by Mayer,[3] aim at a mild erythema reaction with each dose applied. To secure this they use a source of light with a great intensity of ultraviolet energy and avoid overheating the body by using short and intense exposures. When desquamation of skin occurs, treatments are interrupted until it ceases. When the skin no longer reacts to the mercury quartz light, the long flame carbon arc is used, later changing to carbons impregnated by various metals. Their method requires only fifteen minutes maximum radiation front and back in contrast to the Finsen method where a two hour exposure of artificial light is the rule.

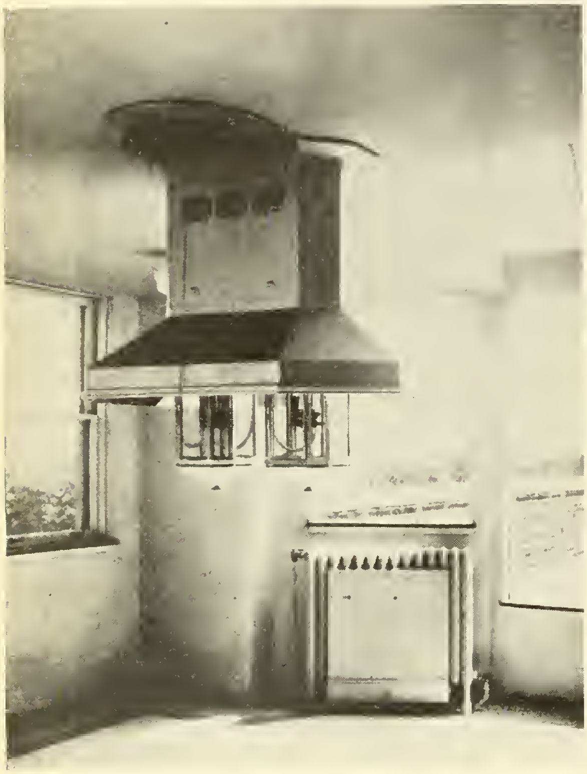

Fig. 8. 60 Ampere Twin Arch Carbon Arc lamp with the Corex-D filter used by Dr. Bosworth.

With a new air-cooled quartz mercury light, Mayer[3] on a purely emperical basis begins with a three minute exposure at a distance of thirty-six inches from the body. He applies two exposures in front and two behind and a fifth one over the area of disease. Exposures are increased by one minute a day until twenty minutes over each area "front and back on all five parts is given." This makes a total exposure of 100 or more minutes. When the twenty minute period over each area is reached, the quartz burner is then lowered about one inch every day until it is eighteen inches from the skin. As the lamp ages the length of the exposures can be increased. The room temperature is maintained at about 70° F. and moving air provided by means of proper ventilation. When necessary, heat is added. In addition to general body exposures with the air-cooled mercury vapor light, local applications of the water-cooled mercury vapor light are used in superficial forms of tuberculosis.

Because of a large number of patients to be treated, we ray the entire body at one exposure progressing in the manner outlined by Mayer, thus reducing the time required for a treatment of each patient from 100 minutes to forty minutes. This enables a larger number of patients to be treated per lamp per day than the other method.

The technic in the use of the water-cooled quartz mercury lamp varies also with the lesion to be treated and the therapist. Some physicians prefer to radiate patients every day with very small doses while others use larger doses and only radiate once or twice a week. The results obtained with either method are about the same. In general, the exposure with this lamp is measured in seconds as compared with minutes for the air-cooled lamp.

The Finsen group using the carbon arc begin with a fifteen minute radiation, front and back, and then increase the radiation fifteen minutes per day front and back until exposures of two hours daily are reached. The distance from the lamp varies with the heat tolerance of the individual. The treatment is frequently accompanied by sweating and is often terminated with a sponge bath. Additional local exposures are made when possible. When carbons are impregnated by various metals, different types of rays are emitted and the amount of radiation used depends upon the skin erythema desired and the general constitutional reaction of the patient to light therapy. With a 90 ampere Schwartz carbon arc light, beginning exposures are usually limited to half a minute with perhaps the maximum exposure of thirty minutes.[3] With the 60 ampere Eveready carbon arc lamp with a Corex-D filter (Fig. 8) and at a distance of 55 to 68 inches from the patient, Bosworth[33] recommends that the body be zoned as it is for solar radiations and that exposures be gradually increased as they are under light therapy. However, when the chest has been exposed five minutes, he then recommends that general body radiation be limited to five minutes, front and back, increasing five minutes a day front and back until thirty minutes exposure anterior and posterior have been reached.

It is understood that these are merely suggestions for the technic of the ordinary exposures and that each patient represents an individual problem. An over-exposure to either sunlight or artificial light will result in tissue injury rather than in stimulation. This injurious reaction is usually manifested by cutaneous reactions such as blistering, intense burning and systemic reactions, such as fatigue and an increase in the pulse and temperature rate which persists. This last reaction is probably due to an intense focal reaction similar to the focal reaction produced from an over-dose of tuberculin. Therefore, great care must be exercised to see that the individual does not receive a greater amount of radiation than he can tolerate. In some instances it may be advisable to radiate the patient every day but to reduce the length of exposure, and in others to radiate the patient only every other day. In all instances, individualization is necessary and the physician is to be guided chiefly by the skin reaction and the general reaction of the patient to light therapy.

RESULTS

After nine years experience in heliotherapy, both natural and artificial, we agree with those who believe that where general body radiations are indicated, the best results will be obtained from natural sunlight. We have had ample opportunity to observe that in the fall, at the end of a summer's sun, our patients are in much better condition than they are in the following spring after several months of quartz mercury radiation. This, of course, is to be expected because as Coblentz[8] states, "physically there is no comparison between this type of radiation and that of the sun and it is hardly to be expected that these two sources of light will give the same results in all types of treatment." As the white flame carbon arc with a Corex-D filter emits a source of light which is more like sunlight than that obtained from any other artificial source, it is natural to expect the results from this type of lamp to be more similar to those obtained from sunlight than those obtained from any other type of artificial light.

The results to be expected in groups 1 and 2 vary, of course, with the type, extent and severity of the extra-pulmonary lesions and the pulmonary complications. Excellent results with natural and artificial heliotherapy, using both general and local radiations, have been obtained in tuberculosis of the skin. Tuberculosis of the superficial glands, as a rule, responds very well to general and local radiations with sun and artificial sources of light. Local X-ray treatments increase fibrosis and reduce the period of treatment.

In very early cases of bone and joint tuberculosis, before bone destruction or erosion of cartilage has occurred, good results can be obtained from heliotherapy plus good orthopedic sense, if the treatment is continued long enough. Many of such patients will have a functioning joint. If the process has gone on to bone destruction or erosion of the cartilage, a more permanent result can be obtained as well as the length of treatment reduced if surgery is added at the proper time. In such cases an ankylosed joint results.

In extremely early cases of renal tuberculosis, before the lesion has ulcerated into the pelvis, or the function of the kidney impaired, good results may be obtained with heliotherapy combined with bed rest. In unilateral lesions where there is ulceration into the kidney pelvis, heliotherapy, before and after nephrectomy, combined with bed rest will improve the results. In bilateral cases of renal tuberculosis, heliotherapy is only palliative but often produces surprisingly good clinical results, even including the disappearance of tubercle bacilli from the urine. Sooner or later most of these patients relapse. Genital tuberculosis is usually secondary to a renal infection although it can occur without it. When the renal focus is removed and the external evidence of genital tuberculosis, such as epididymitis is properly treated, including the use of heliotherapy, the lesions in the bladder, prostate and seminal vesicle usually heal rather promptly under heliotherapy, plus other factors of sanatorium regimen.

Tuberculosis of the peritoneum does unusually well under heliotherapy. When the focus is removed later, there is very little possibility of recurrence of the disease.

Intestinal tuberculosis does very well under general heliotherapy supplemented by local applications with the air-cooled mercury lamp and a suitable diet. Whether carbon arc lamps with a Corex-D filter will prove more valuable in this type of lesion or not can only be determined through more study.

Tuberculosis of the middle ear and the larynx give excellent results under general solar radiations plus local radiations with the water-cooled quartz mercury light.

Tuberculosis of the anus and lower rectum give good results when general solar radiations are combined with adequate surgery at the proper time.

In pulmonary tuberculosis, group 3, the results to be obtained from natural and artificial sources of sunlight using general body radiations are excellent and surpass those obtained in any other form of treatment.

In group 4 the results in selected cases with properly supervised heliotherapy, both natural and artificial, are good. We have been very fortunate in having many cases go on to more complete fibrosis under this type of treatment than when the ordinary sanatorium treatment was used.

As heliotherapy is contra-indicated in group 5, only poor results can be expected.

Appreciation is due Dr. Wilhelm Strenstrom, Associate Professor of Biophysics, University of Minnesota, Minneapolis, for valuable criticism of that portion of this article which deals with the physical characteristics and physiological effects of light.

IMPAIRMENT OF VISION FOLLOWING HEAD INJURY*

ARTHUR EDWARD SMITH, M.D., F.A.C.S.
Minneapolis

A NUMBER of factors have combined, during the past two decades, to bring about a considerable increase in the relative number of traumatic cases encountered in surgical practice.

Modern industry provides its share of these, and traffic hazards, since the advent of the automobile, have greatly increased the incidence of injuries, and given rise to a relative as well as an actual increase in the number of traumatisms involving the head. About 75 per cent of individuals who have sustained head injuries of any consequence complain afterward of visual disturbances. These may comprise anything from a slight, transient obscuration of sight to complete blindness.

Naturally these sequelæ frequently form the basis for claims for compensation or damages. It devolves upon the examining surgeon to determine the exact nature and extent of the loss of visual function, to decide whether the existing impairment is due in part or entirely to the particular injury in question, and to exclude malingering.

Injury to the visual mechanism manifests itself in various ways. Thus we may encounter in these patients:

1. Impairment of central vision.
2. Defects in the peripheral fields of vision.
3. Impairment or loss of function of the cortical centers or association fibers, causing conceptual blindness (mind blindness or object blindness) in which the patient can see objects, but fails to recognize them for what they are.
4. Loss of ability to distinguish colors.
5. Motor derangements, including ptosis, paralysis of the extrinsic ocular muscles, interference with the normal pupillary reactions, loss of accommodative power, impairment of conjugate ocular movements, etc.
6. Nystagmus.
7. Purely psychic affections of the sight, such as occur in hysteria, traumatic neurasthenia, etc.

In the trial of cases involving litigation over the alleged effects of head injuries great stress is always laid upon the presence or absence of demonstrable skull fracture, although it is an obvious and well known fact that this is altogether secondary in importance to the question of the nature and extent of the injury to the brain. Extensive fracture of the skull may be present in cases in which there are no subsequent evidences of any brain trauma of consequence, and there are, of course, many cases of serious, and even fatal, injury in which there has been no loss of osseous continuity. For instance, those cases of fatal head trauma in which the only autopsy findings are multiple punctate hemorrhages into the deeper structures of the brain, seem to be observed only in the absence of skull fracture.

Much of the experimental work which has been done in an attempt to work out the physics and mechanics of head injuries has been without very significant results. This is natural in view of the fact that in cadavers (which can rarely be examined in the fresh condition) the rigidity and inertness, the muscular atony, absence of circulation and deflux of the cerebrospinal fluid give rise to physical and mechanical conditions which are quite different from those which exist in the living subject. However, some of the studies along this line, such as the experiments of Felizet on the elasticity of the cranium, the work of Coppez on the mechanism of chiasmal injuries, etc., have been of definite value.

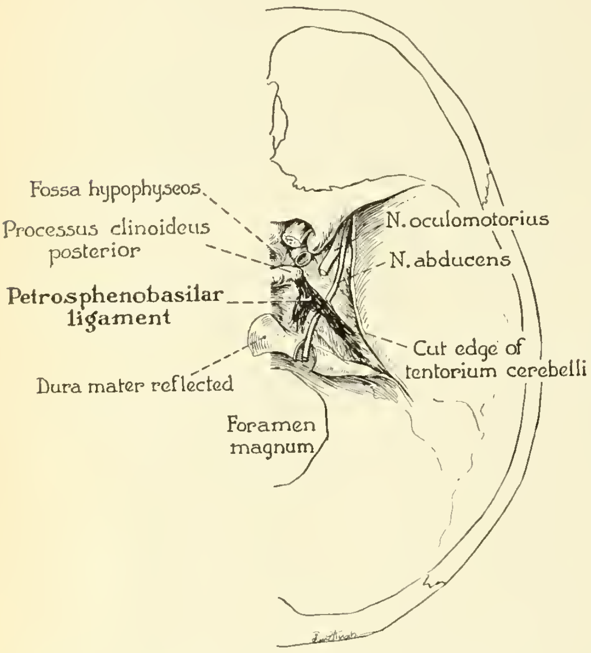
Because of the structural characteristics of the skull, a vault affording almost complete bone continuity, with closed sutures and with a base weakened by many openings for nerves and blood vessels, in blows or falls upon the vertex of the head, the force naturally tends to be transmitted to the base. This frequently causes a basal fracture with or without a coincident fracture of the vault.

The anatomical relationship of the optic nerves, chiasm, optic tracts and nuclear centers with the skull base, especially in the region of the middle fossa, explains the frequency with which these basal fractures are followed by disturbances of vision.

---

*Presented before the annual meeting of the Minnesota State Medical Association, Minneapolis, May 6, 1931.

The force of blunt traumatism to the skull, from any angle, tends to pass around in radiating directions, causing cracks with varying degrees of separation of the bone. These cracks naturally tend to follow the weaker structures lying between the bony buttresses, and hence to involve the fossæ.



Fossa hypophyseos
Processus clinoideus posterior
Petrosphenobasilar ligament
Dura mater reflected
Foramen magnum
N. oculomotorius
N. abducens
Cut edge of tentorium cerebelli

Fig. 1. Dissection showing relationship of abducens nerve to petro-spheno-basilar ligament.

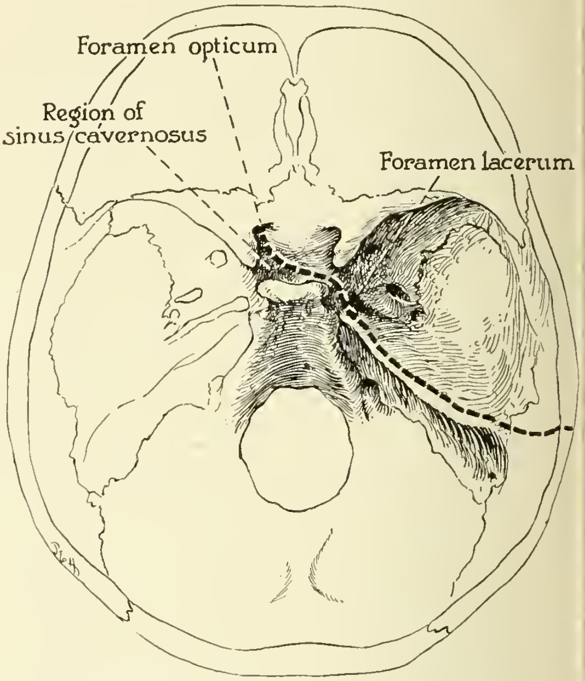


Fig. 2. Ajello's case of fracture of the right middle fossa extending into the optic foramen of the opposite side.

Fractures which irradiate from the parietotemporal region to the corresponding middle fossa are much the most frequent of all fractures extending to the base. This is due to the extreme thinness of the bone in this part, and to the fact that at this point is found the greatest distance between the two nearest reinforcements—the orbito-sphenoidal pilaster in front and the pilaster of the petrosa and mastoid tuberosity behind.

In fractures of the middle fossa, particularly those which injure its posterior portion, the pyramid formed by the petrosa is almost always involved. The line of fracture usually follows a course parallel to the axis of the pyramid. The inelasticity of the pyramid, the numerous canals which traverse it, and its oblique median slant make this region particularly vulnerable. In fractures parallel to the axis of the pyramid the apex is almost always involved, especially when the bone is sharpened into a simple apophyseal lancet or, as in some cases, is joined to the petrosa by a small osseous pedicle.

Due to the firm attachment of the petrosphenobasilar ligament (which connects the apex of the petrosa to the dorsum of the sella and to the basilar process of the occipital bone), the apex is not able to take part in the rotation of the pyramid, a condition liable to occur in traumatisms of the median fossa. The anatomy of Dorello's canal is of interest in this connection. Vail says, "Between the spina sphenoidalis and the processus clinoideus posticus there is a sinus with its concavity directed superiorly and laterally. It is bridged over by the petro-spheno-basilar ligament. In this space lie the abducens nerve and the inferior petrosal sinus where it empties into the cavernous sinus. The abducens lies in the lower boundary of this area, often being confined to the angle which the spina sphenoidalis makes with the upper margin of the pyramid of the petrous bone, which at this point is somewhat flattened from above. After leaving Dorello's canal the abducens makes a slight bend and enters the cavernous sinus, where it now lies in near relationship to the carotid artery."

The trunk of the abducens nerve (Fig. 1), passing beneath the ligament and in close contact with the bone, is almost always injured in fracures in this region. This gives rise to one of he most frequently encountered traumatic eripheral paralyses in basal fractures—that of he external rectus.

In most fractures extending into the petrous ortion the apex is found to be broken and seprated from the rest of the bone for about 3 mm. istance. This corresponds precisely with the ength of the fixed portion of the petro-sphenoasilar ligament.

The majority of fractures of the middle fossa erminate in the foramina of the same side. It ust, however, be remembered that they someimes reach the optic foramen on the opposite ide. Ajello cites a case of fracture of the right edian fossa extending completely across the ength of the pyramid bordering its upper marin and passing obliquely into the corresponding oramen lacerum. From here the fracture scended the internal face of the cavernous sinus nd ran across the sella into the optic foramen f the opposite side (Fig. 2).

The extent of fractures of this kind is someimes overlooked at autopsy if the whole base f the cranium is not completely denuded of the ura, which is closely adherent to the subjacent one, often concealing slight and incomplete lines f fracture.

In basal fracture there is frequent participaion of the walls of the orbit. Of eighty-six cases Von Holder found seventy-three in which the rbit was involved. The majority of orbital fracures extend into the optic canal and foramen. The anatomical relationship of the optic nerve with the foramen and canal is such that the nerve s almost inevitably injured. The meninges of he brain here form three concentric sheaths round the nerve. The inner sheaths are deliate and easily lacerated; the external (dural) sheath adheres very closely to the periosteum of the foramen and the canal, especially to the pper and internal walls, which are very fragile. The spaces bounded by the three sheaths surrounding the nerve are closed anteriorly, but ommunicate directly with the subdural and subarachnoidal spaces of the brain posteriorly, making possible the violent penetration of the endocranial fluid in severe injuries of the head. This explains the microscopic findings, since the penetration of the cerebrospinal fluid, besides causing expansive elevation of the sheath of the nerve and rupture of its trabecular network, gives rise to separation, contusion and laceration of the nerve elements and disorientation of their molecular relationship. In extravasation of blood into these spaces, the source of the hemorrhage may be the subdural cranial space, the ophthalmic artery or its branch, the central artery of the retina either before or after it enters the nerve about 12 mm. from the eyeball.

In Miceli's case, in which the patient died of pneumonia about six weeks after the injury, (fracture involving the right optic canal), macroscopic examination showed the optic nerve to be thickened in the form of a club with the most swollen part toward the anterior extremity. Microscopically there was increase in the intervaginal space, more marked toward the distal end. In the vicinity of the lamina cribrosa the nerve fibers were tightly packed although in the tracts small vacuoles of varied form were interposed. There were ovoid lacunæ, lined with endothelium only from the side of the arachnoid. Some of these lacunæ penetrated like a fissure into the dural sheath.

The mechanism of injury to the optic chiasm is of particular interest. That cranial traumatisms so often fail to affect the chiasm is due to the latter's being so placed that it is seldom touched by the lines of fracture or splinters of bone.

The chiasm does not rest upon a bony surface but is encased in an arachnoid covering and situated above the anterior part of the tentorium of the hypophysis. It does not have direct connection with the diaphragm of the pituitary body, from which it is separated by the cisterna basalis of the subarachnoid space. This intervening space varies from 4 to 10 mm.

Hence, the line of fracture, even if it passes through the sphenoid body and optic groove, does not touch the chiasm (Fig. 3). Radiograms do not show bony splinters in this region nor have they been found at autopsy. It is probable that hemorrhage seldom exerts enough pressure on the chiasm to destroy the function of the crossed visual fibers.

Certain types of fracture are particularly liable to be associated with injuries of the chiasm. These are fronto-sphenoidal fracture, anterolateral fracture with depression of the external orbital wall, and petro-occipital fractures extending to the spheno-petrosal suture.

The fronto-sphenoidal fracture is especially common in automobile injuries and is usually the result of violence to the frontal region. As a rule, in these cases, the optic nerve is injured at the canal, causing a more or less complete monocular blindness promptly followed by atrophy; occasionally, however, a bitemporal hemianopsia is observed. The mechanism of the production of these hemianopsias is apparent.

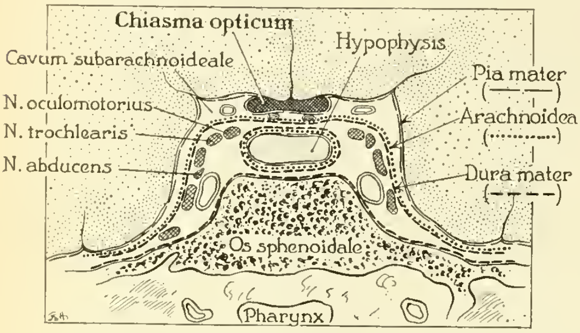

Fig. 3. Relationship of chiasm to hypophysis and os sphenoidale.

In his experiments on the elasticity of the cranium, Felizet has shown that antero-posterior blows may increase the transverse diameter as much as 8 millimeters without fracture occurring. In more severe traumatisms, which would inevitably be followed by fracture, the transverse "spread" is still greater. The ethmoid is depressed from front to back and is fractured in the same direction. The two optic canals are thus violently separated from each other, pulling away with them the optic nerves (Fig. 4). Coppez has demonstrated that the vulnerable points of the chiasm are the anterior angles at the attachments of the optic stalks. The nerve is firmly adherent to the walls of the optic canal and, if the traction induced by the "spread" is sufficient, the chiasm suffers a saggital laceration which is, of course, followed by a bi-temporal hemianopsia. If some of the bundles of crossed fibers have been preserved there will be small areas in the temporal fields where vision will be intact. The macula is not, as a rule, involved and central vision usually remains unaltered.

The second type of fracture referred to above; *i.e.*, antero-lateral fracture with depression of the external orbital wall, is one frequently observed following automobile injuries in which a wheel has run over the head. In these cases, if the nerve is torn at the anterior orifice of the canal on the same side as the injury, there is a simple loss of sight in the one eye. If, however, there should be an extensive fracture of the canal, the tearing away of the nerve takes place farther back at the angle of the chiasm, adding a loss of function of the temporal field in the other eye to whatever damage may have been done to the eye on the side of the injury.

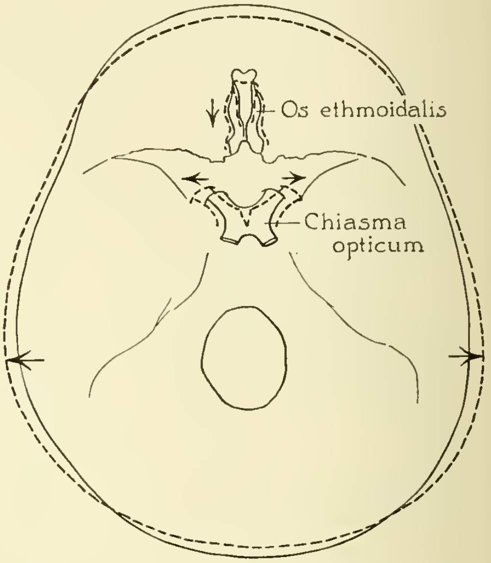

Fig. 4. Schematic drawing illustrating "spread" of optic foramina in compression of the cranium from force applied antero-posteriorly.

The third type of fracture mentioned (petro-occipital, extending to the spheno-petrosal suture) tends to follow a line parallel to the axis of the petrosa. The fracture line often reaches the sella turcica, running from behind forward and from the lateral to the mesial border, that is, perpendicular to the optic nerve on the same side. In this type of fracture, too, since the separation occurs in the direction of the course of the nerve, it may be assumed, that the nerve is suddenly and violently pulled by the spread of the bones, the force being transmitted to the chiasmal fibers as previously described.

Of particular interest in connection with the mechanism of injuries to the cortical portion of the visual apparatus are the cases of pressure atrophy of the brain following cerebral trauma.

Temple Fay in a recent article elucidates the underlying causes of these frequently overlooked or incorrectly diagnosed conditions. He demonstrates the effects of injury to the mechanism concerned in the secretion of the cerebrospinal fluid (the subarachnoid villi and pacchionian bodies) and shows the importance of encephalography in the later determination of the degree of damage to the cerebral cortex.

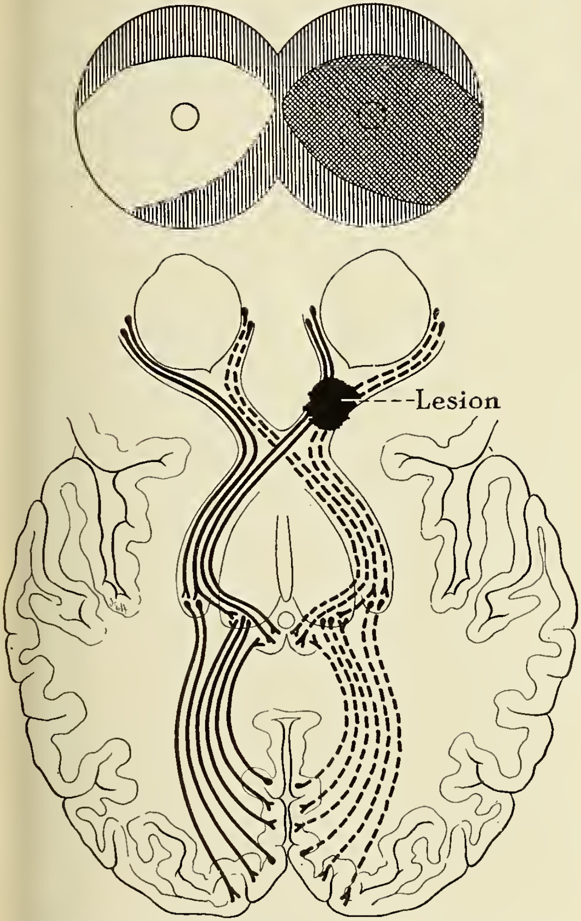

Fig. 5. Visual field in total destruction of optic nerve between retina and chiasm.

The experience of surgeons during the Great War has materially enriched the literature concerning the visual effects of cranial injuries even though, at that time, the examination of patients immediately following the trauma was, as a rule, necessarily superficial. Under the circumstances, detailed study of visual disturbances with careful mapping of fields, etc., could not be undertaken until considerable time had elapsed.

There is still much to be learned in regard to cerebral localization so far as the visual apparatus is concerned. For example, considerable difference of opinion exists in regard to the cortical representation of the macula. In the light of what knowledge we now possess, it is, however, possible to locate, with considerable exactness, a lesion anywhere along the visual pathway from the retina to the higher cortical centers. These lesions are classified by Bing as follows:

1. Lesions of the retina.
2. Lesions of the optic nerve.
3. Lesions of the chiasm.

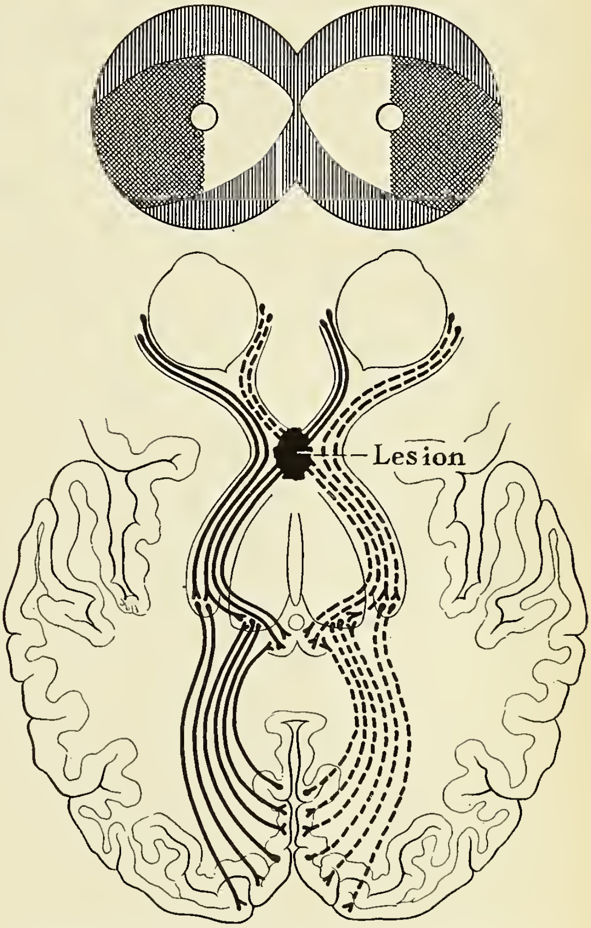

Fig. 6. Visual field in destruction of mesial fibers of optic chiasm.

4. Lesions of the optic tract, primary visual centers and radiation of Gratiolet.
5. Lesions of the area striata (cortex of the cuneus and upper part of the lingual gyrus).
6. Lesions of the convexity and white matter of the occipital lobe and the angular gyrus.

RETINA

Commotio retinæ is usually due to direct contusion of the eyeball, but cases of transient loss of vision may occur after head injuries in which there is no apparent injury to the globe. These may, rarely, show a slight cloudiness of the fundus but usually the ophthalmoscopic examination is negative.

A number of cases of retinal or pre-retinal hemorrhages following head trauma have been reported. Papilloedema, when it occurs, usually appears on the fourth day after the injury. It may, on rare occasions, be found as early as the third day or as late as the eighth day. Forrester, in examining the fundus in a large series of cases shortly after injury, did not observe a single case of choked disc.

OPTIC NERVE BETWEEN GLOBE AND CHIASM

Monocular blindness, exclusive of direct injury to the eye itself, is caused only by a lesion at this site (Fig. 5). In total destruction of the fibers the blindness is, of course, complete. If only part of the nerve fibers are destroyed an irregular restriction of the field of vision, scotomata, etc., will be found. In complete destruction pupillary responses are not evoked by the affected eye but may be by the other eye, whose perception of light is unimpaired. Injuries at this point are promptly followed by atrophy of the nerve. The nearer to the disc the injury occurs the sooner the atrophy ensues.

CHIASM

If the lesion resulting from the injury involves, as it usually does, only the mesial portion of the chiasm, there is a partial or complete destruction of the decussating fibers coming from the nasal halves of the retina. The result is a bitemporal heteronymous hemianopsia (Fig. 6).

If the external portions of the chiasm are destroyed, the mesial fibers remaining intact, there is suppression of the outer halves of the retinæ, giving rise to a nasal heteronymous hemianopia. Although rare, this may occur as a result of disease, but it is practically unknown in traumatic cases. Apparently the late war furnished only one case of a traumatic lesion of this kind and that was not very thoroughly studied.

A lesion destroying exactly one-half of the chiasm would cause a complete loss of sight in the eye on the injured side and a temporal hemianopsia in the other eye.

Optic atrophy (affecting the corresponding sectors of the discs) does not appear until some time after the injury. The atrophy is more marked in the disc contralateral to the injury because of the crossed bundle being larger than the non-decussating one.

OPTIC TRACT, PRIMARY VISUAL CENTERS AND RADIATIONS OF GRATIOLET

Destructive lesions here cause homonymous lateral hemianopia for the halves of the visual field on the side opposite to the lesion (Fig. 7).

It is possible to determine whether or not the injury has involved a point peripheral to that at which the reflex fibers to the Edinger-Westphal nucleus are given off by eliciting the hemianopic pupillary reaction (Wernicke's phenomenon). This is best carried out by using a small pocket flashlight with the end covered except for a small opening emitting a narrow pencil of light rays. This is held at about 45 cm. from the point of fixation through either half of the visual field while a disc of dull black cardboard or blotting paper is held on the side of the nose in order to prevent the reflection of rays toward the normal half of the retina. The test must, of course, be carried out in a darkened room.

If the injury has caused a lesion peripheral to the point at which the reflex fibers to the pupillary nucleus are given off, the light thrown on the blinded half of the retina will not cause a contraction of the pupil, its access to the oculomotor nucleus being blocked. On the contrary, if the lesion is central to this point, the pupil will react to the light since the nerve impulses are carried as far as the centers for the iris sphincters, although not being able to reach the cortical centers of vision.

AREA STRIATA (CORTEX OF THE CUNEUS AND UPPER PART OF THE LINGUAL GYRUS)

If the whole visual area of the cortex on one side is destroyed (Fig. 8), the result is the same as in a destruction of the thalamo-occipital fibers on the same side, *i.e.*, a homonymous lateral hemianopsia with retained pupillary reaction. If only a part of one cortical area is destroyed only a segment of the lateral field is obliterated, causing a quadrant hemianopsia or symmetrically situated scotomata.

CONVEXITY AND WHITE MATTER OF THE OCCIPITAL LOBE AND OF THE ANGULAR GYRUS

"Bilateral lesions involving the visual memory centers in the cortex or the association fibers which pass thither from the area striata cause conceptual blindness, a condition in which the patient can see objects as flat surfaces or as solid bodies but is unable to recognize them for what they are or to state their objects and uses.”

Injuries to the angular gyrus cause alexia (inability to read) and sometimes a conjugate deviation. In case of a destructive lesion of the gyrus the deviation is toward the side of the lesion, the angular gyrus being a thoroughfare for fibers which connect the visual area with the frontal centers for the ocular muscles.

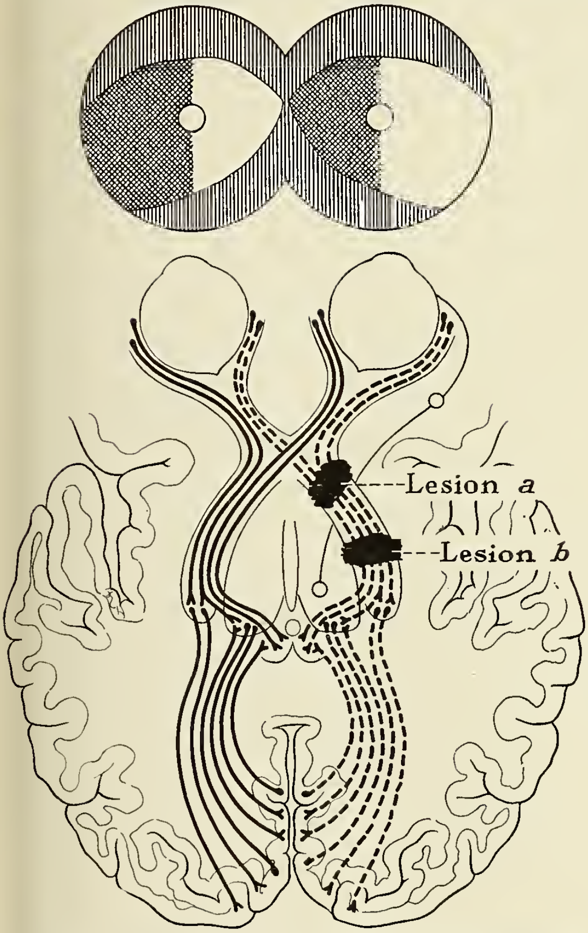

Fig. 7. Visual field in destruction of the right visual tract. (Lesion “A” peripheral to Edinger-Westphal nucleus —causing homonymous hemianopia with abolished hemianopic pupillary reaction.) (Lesion at “B” giving rise to same field changes with retained pupillary reaction.)

LOSS OF ABILITY TO DISTINGUISH COLORS

Head trauma may be followed by loss of the color sense. This may be transient or permanent and may affect all or only a part of the visual field. Color blindness may be the only visual symptom complained of or it may be associated with impairment of central or peripheral vision. In traumatic cases, the fields of vision for color contract earlier that those for form, the nerve fibers concerned in the conduction of colors being apparently more sensitive to the effects of pressure than those concerned in the transmission of the perception of form. Suker says that lesions central to the chiasm and tract are very seldom preceded by color changes and ascribes this to the fact that beyond the primary centers the form and color fibers are more widely separated than they are in the nerve, chiasm and tract.

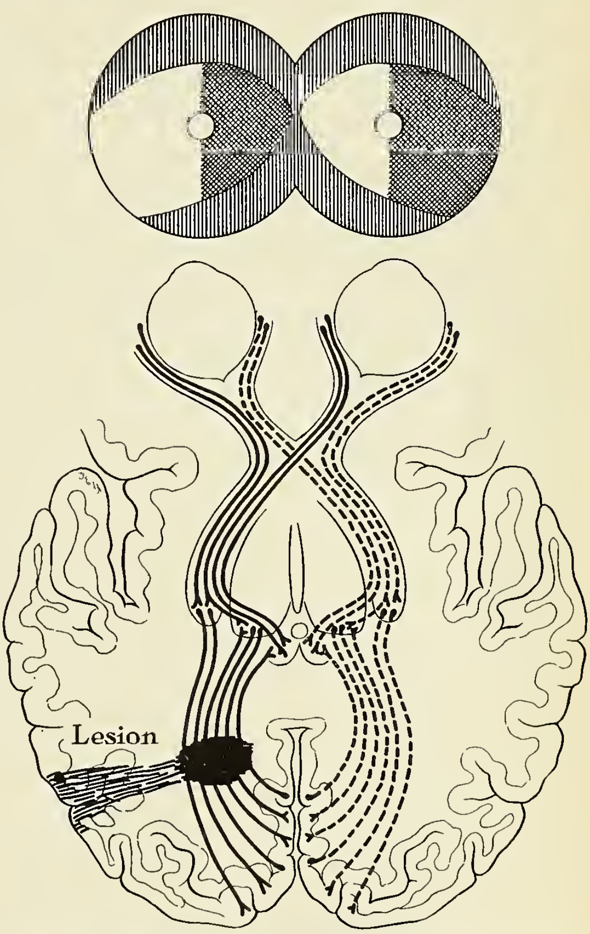

Fig. 8. Fields in destruction of white matter of occipital lobe. (Homonymous hemianopsia with alexia.)

MOTOR DERANGEMENTS

These may affect the lids, the muscles concerned in ocular movement or the intrinsic muscles governing the pupil and accommodation.

Paralysis of the orbicularis palpebrarum occurs rather frequently in injuries of the facial nerve. Parsons says that unilateral facial paralysis is the most common cranial nerve lesion in fractures of the skull base. The injury may affect the supra-nuclear or infra-nuclear portion of the nerve. As a rule the orbicularis is not involved in lesions situated above the nuclear center. These paralyses are important clinically since the defective lid closure causes the cornea to be exposed to desiccation, especially during sleep. This is sometimes followed by a keratitis e lagophthalmo with subsequent impairment of sight.

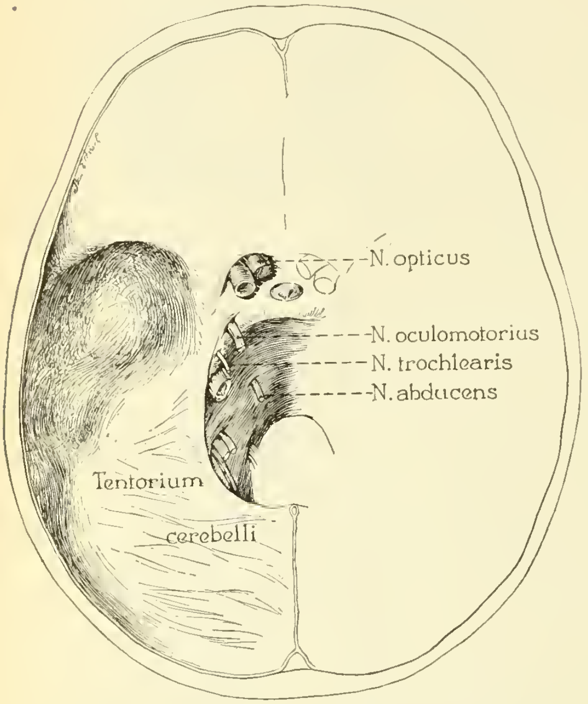

Fig. 9. Dissection of skull base showing relationship of oculomotor, trochlear and abducens nerves.

Paralysis of the levator palpebræ superioris sometimes follows head injury. The trauma may affect the nerve close to the lid, in which case a simple ptosis will follow. In case the injury to the third nerve has affected a point above where the levator fibers are given off, some or all of the other muscles innervated by the oculo-motor will be involved.

Interruption of the sympathetic oculo-pupillary innervation is evidenced by the Bernard-Horner syndrome.

1. "Sympathetic" ptosis from paralysis of the involuntary portion of the levator of the upper lid.

2. Enophthalmos from paralysis of the musculus orbitalis. (This may be slight or not demonstrable at all.)

3. Paralytic miosis from interference with the function of the dilating fibers of the pupil.

This syndrome is a rather rare sequel of head injury. In one case seen by the writer the patient gave a history of having been injured in an automobile accident. He was thrown against the side of the car, striking the left side of his head against the frame. He was dazed for a while but only unconscious for a few moments, if at all; there was no evidence of skull fracture; the skin was unbroken; there was a bruise over the left temple and a discoloration of the left upper eyelid—typical Bernard-Horner syndrome. Neurological findings were otherwise negative. When the patient was last seen, two months after the injury, the condition was unchanged.

The most frequently encountered of the traumatic paralyses of the extrinsic muscles are those of the sixth nerve (abducens). This nerve is particularly vulnerable because of its long course, its exposed position, and its relations to the petrous portion of the temporal bone and the petro-spheno-basilar ligament (Fig. 9).

In destructive injuries there is complete paralysis of the external rectus muscle with inability to abduct the eye. Abducens palsy follows in about 4 per cent of all basal fractures. Because of the supranuclear innervation of the ocular muscles being almost altogether bilateral, unilateral paralyses are nearly always due to nuclear or infranuclear lesions.

Post-traumatic lesions of the third nerve (oculomotor) are less frequent, occurring in about 2 per cent of basal skull fractures. All, or only a part, of the muscles supplied by the nerve may be affected. In ophthalmoplegia totalis there is a ptosis (from paralysis of the levator) and the eye is turned strongly outward and a little downward from the action of the muscles not supplied by the third nerve, *i.e.*, the external rectus and the superior oblique. Strictly speaking, of course, a total ophthalmoplegia would involve the abducens and trochlearis as well. The pupil is dilated and immobile and the power of accommodation is lost. The paralysis may affect only the extrinsic muscles, leaving the mechanism of the pupil and accommodation intact, or it may affect only the sphincter of the pupil and the ciliary muscle. By reason of its extensive connection with the petrosa the third nerve shares, in a measure, the vulnerability of the abducens and trochlearis; it is particularly liable to be injured in fractures running into the superior orbital fissure. The nerve enters the fissure at its largest part close to the optic foramen and hence it is frequently involved in fractures of this region.

The fourth cranial nerve is affected in about 1 per cent of basal fractures. In patients who have sustained an injury to the trochlearis there is a characteristic tendency to turn the head toward the shoulder of the affected side and drop the chin in an effort to overcome the double vision. The image seen by the paralyzed eye is lower than that of the injured, and its upper end is tilted inward.

Reflex immobility of the pupil (Argyll-Robertson's sign) may occur as a result of cranial trauma. It is usually transitory. When due to an njury of the reflex centers it is bilateral. When bserved in connection with injury to the orbit t is usually unilateral.

In injuries of the association centers (Fig. 10), there are encountered the type of paralyses which do not affect the muscles individually but which interfere with associate movements. This may take the form of an inability to converge, o look to the right or left, or upwards or downwards. In injuries causing destruction of the ibers of the cortico-nuclear tract above the pons, he patient looks toward the side on which the esion is located; on the contrary, if the lesion is n or below the pons (the fibers of the tract aving crossed) he looks away from the injured ide.

Compensation usually occurs in conjugate aralyses which are, therefore, as a rule, not ermanent. Riley says that there may be a aralysis of lateral deviation without any demontrable lesion of the sixth nerve nucleus, and tates that the center for lateral deviation is not dentical with the abducens nucleus, but is ituated in the near vicinity. He has observed ilateral loss of conjugate gaze in midline pon-ine lesions.

NYSTAGMUS

Nystagmus is an infrequent sequel of head injuries. Blakeslee observed it in thirteen out of ix hundred and ten cases. It is an early symptom in those cases in which it occurs. The ystagmus following brain-stem lesions is apt to e permanent and thus may affect the future earning power of the injured person. That following injury to the labyrinth or cortical centers is usually transitory. Nystagmus observed in a person who has sustained a head injury is not necessarily a consequence of that injury. It may be congenital or due to some pre-existing condition such as labyrinthine disease, diseases of the central nervous system, such as multiple sclerosis, cerebellar lesions, etc. It is sometimes observed in alcoholics and in drug addicts and may occur as an occupational neurosis, as in coal miners.

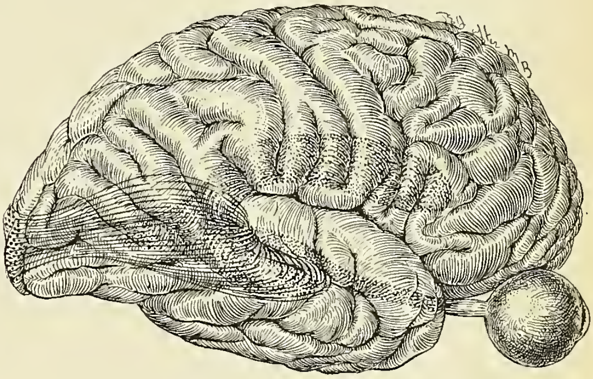

Fig. 10. Projection of visual tracts on brain surface. (After Max Brödel.)

Head trauma is also sometimes followed by simple conjugate oscillatory movements of the eyeballs. In such cases the oscillations are simple and irregularly grouped, lacking the characteristic rythmic phases of true nystagmus.

PSYCHIC AFFECTIONS OF THE SIGHT FOLLOWING HEAD INJURY

These may be grouped under two general headings: those cases due to hysteria, in which the underlying principle is that of inhibition; and those which are the result of a traumatic neurasthenia, in which the essential element is fatigue.

The theoretical differentiation of these conditions is simple, but the establishing of a valid clinical diagnosis may offer considerable difficulty. Hysteria and neurasthenia may co-exist in the same patient; a tendency to malinger may complicate either condition, thus adding to the difficulty in arriving at a conclusion.

The particularly interesting feature of ocular hysteria, as of that affecting other parts of the body, is its simulation of a wide range of organic conditions. Head's classification of the ocular manifestations of hysteria is as follows:

1. Disturbances of sensibility
    - Anesthesia and hyperesthesia of the skin of the lids, cornea and conjunctiva
    - Photophobia
    - Neuralgia
2. Visual disturbances
    - Diplopia
    - Polyopia
    - Erythropsia
    - Macropsia and micropsia
    - Amblyopia and amaurosis
    - Hemeralopia (from reduced retinal function)
    - Visual field disturbances
3. Disturbances of motility
    - Ptosis
    - Blepharospasm
    - Strabismus
    - Spasm of accommodation
    - Miosis and mydriasis
    - Hysterical cycloplegia
    - Accommodative asthenopia
    - Nystagmus
    - Conjugate deviation
    - Convergence insufficiency
    - External ophthalmoplegia
4. Secretory disturbances
    - Epiphora and lacrymation
    - Dryness of conjunctiva
5. Subjective complaints
    - Insomnia
    - Vertigo
    - Inability to concentrate

The characteristic perimetric changes in hysteria are:

1. Concentrically contracted fields
2. Tubular fields
3. Reversal of color fields

It is of interest to note that even in extreme contraction of the fields, these hysterical patients have no difficulty in orientation such as accompanies similar contractions due to organic lesions.

Head injury in a neurasthenic person or one with a neurasthenic tendency may be followed by the exhaustion phenomena characteristic of ocular neurasthenia. These phenomena may take the form of an incapacity of the eye for continuous exertion in close work, pain on continued reading, sensitiveness to light, etc. The characteristic spiral fatigue field of Von Reuss is frequently encountered. In hysteria the involvement of the field is usually constant, while in neurasthenia it is variable.

PRESIDENT'S LETTER

THE present unprecedented program for veteran's relief was already foreshadowed in 1920 when the United States Public Health Service was replaced by a Veteran's Bureau for the administration of disabled veterans' affairs.

Why did not the American Medical Association committees who approved those original medical policies of the Veterans' Bureau, propose, instead, their enlightened 1931 insurance plan for the care of veterans?

This is a question that the men who are working for the Shoulders insurance proposal for modifying the government veterans' program are going to meet often in the next few months particularly from officials of the disabled veterans' associations. These officials have been working all these years, they tell me, for just such liberalizations of the Veterans' Bureau policy with regard to the war disabled as the Shoulders plan would guarantee to every veteran whatever the origin of his disability with one sweeping gesture.

The physician and organized medicine in general undoubtedly missed a brillant opportunity to perform a great public service when they failed to see the obvious trend in those early crowded days of random veterans' relief measures.

That it is much easier to see obvious trends after these trends have unmistakably revealed themselves goes without saying. War was never before fought on the scale of the World War and war relief drawn to the scale of the present Veterans' Bureau program was hardly even to be imagined. It is not to be wondered at, probably, that few physicians or anybody else foresaw the magnitude to which the program would grow in less than fifteen years from the date of the armistice.

To do anything now to divert the feverish hospital building program of the government, to check the debilitating policy of paternalism toward the ex-soldier will be harder, much harder, than ten years ago or five years ago or even two years ago before the appropriation of the last congress was made.

We must recognize this fact at the same time we acknowledge, also, that it does not relieve us from the obligation of doing what we can now.

The resolution offering disability insurance in place of unlimited government hospitalization for ex-service men has the support of many wise men in and out of the medical profession. It was sponsored by H. H. Shoulders of Tennessee at the May House of Delegates meeting of the American Medical Association and it appears to offer a workable solution to the problem of supplying all veterans with medical care for all their ailments without involving the government in a huge system of veterans' hospitals. As explained and commented upon by C. B. Wright in his paper in this issue of MINNESOTA MEDICINE this plan would relieve the government of the enormous expense involved in adequate care for the veterans while the veterans themselves would be at liberty, under the terms of a general disability policy, to get their own treatment where and from whom they chose.

The form that this disability policy might take is by no means confined to the suggestions embodied in the Shoulders resolution. In point of fact, certain inequalities between the treatment of service connected and non-service connected cases implied in the resolution have already been called in question by service men's organizations and will doubtless be adjusted.

The point is that only a fraction of the hospitals have been built that must be built if the Veterans' Bureau is to continue in its present policy, only a fraction of the money spent. If some such scheme as the Shoulders resolution suggests is feasible at all, either now or in the remote future, it should have the active earnest support of every forward looking citizen.

L. Sogge

President
Minnesota State Medical Association.

THE SHOULDERS RESOLUTION

Elsewhere in this magazine is an important aper by Dr. C. B. Wright of Minneapolis in hich is outlined the major arguments in sup-ort of the Shoulders resolution passed in May y the House of Delegates of the American Med-cal Association.

Similar discussions are appearing currently in edical journals all over the country represent-ng the first steps in an important general move-ent among physicians and legionnaires to mod-fy the existing government policy with regard o Veterans' relief.

This new movement pins its hopes upon a system of insurance for veterans by which all who are disabled for any cause may be permitted to avail themselves at their own choice of civilian medical service and civilian hospitalization.

This insurance plan is designed to save the government enormous amounts of money for hospital building and staffing; to protect ex-soldier morale now seriously endangered by the paternalistic policy of the Veterans' Bureau and to find a means for using the already alarming number of empty beds in civilian hospitals.

In point of fact, the current hospital building program of the Veterans' Bureau presents a curious anomoly to anybody who is familiar with the situation in civilian hospitals. For the most part civilian hospitals are not in any sense money making institutions. They are very largely equipped by private gifts and endowments. Their present serious financial straits and the high prices that are necessarily charged to patients are due to the fact that a large proportion of their beds are empty. And yet this huge endowment in equipment is about to be duplicated a hundred times over by the Government and for hospitals that will further empty civilian hospital beds.

It is a question what the poor civilian who can claim no service record and no son or husband or father with a service record is going to do in another decade or two to get his hospital treatment at a fee that he can afford to pay in one life time.

There is one legtimate objection to this new agitation for a change in the administration of veterans' affairs. That is, of course, that it is a little late. Since the last Congress the Veterans' Bureau is already embarked on a greatly magnified new hospital building program. Many thousands of ex-service men with disabilities of non-service connection have already applied for and received all manner of treatment in Veterans' Bureau hospitals. But the difficulty of re-agitating this matter in Congress, of upsetting a new procedure which is rapidly acquiring the force of old precedent, should not deter any really intelligent, determined effort toward changes. When the present appropriations are used up, more appropriations must be made, hundreds more hospitals must be built, untold millions spent, if the Veterans' Bureau is to continue unchecked in its present program.

It is interesting to recall in this connection that a definite concerted medical movement for a change in veterans' policy has been brewing for some time in Minnesota. Resolutions of objection to the government program have passed our House of Delegates several times and the same insurance plan that was later amplified by Dr. Shoulders received considerable attention when it was proposed at the Duluth meeting more than a year since.

MITRAL INSUFFICIENCY

Less than two decades ago the diagnosis of mitral insufficiency was unusually common; today it is rather infrequently made. This turn of affairs has been referred to ironically by some as the result of medical vogue, but this is not the case.

Great strides have been made in recent years toward greater accuracy of cardiac diagnosis, attributable in large measure to critical correlation of clinical and pathologic data, the latter obtained by carefully conducted necropsy. Another important influence which has favorably affected diagnostic accuracy is the changing attitude of members of the medical profession as a whole; the attitude of contented indifference has been supplanted by one of critical inquiry. Even in days recently past, proof of diagnosis was demanded by a relatively small number of members of the medical profession; today, the pendulum, fortunately, is swinging in the opposite direction.

The presence of a systolic murmur, audible over the thorax, in the region of the apex of the heart, previously was considered sufficient evidence for the diagnosis of mitral insufficiency. Few attempts were made to distinguish regurgitation of blood at the mitral orifice, the result of endocardial valvular disease, from regurgitation due to stretching of the ring, such as may occur in hypertrophied and dilated hearts, without endocardial disease. Other causes of apical systolic murmurs, such as sclerosis of valves influences bringing about acceleration of flow o blood, such as occurs in severe anemia and i hyperthyroidism, were not usually distinguishe from true mitral insufficiency.

Richard Cabot's very emphatic statement which appeared in 1926, to the effect that uncomplicated mitral insufficiency is a nonentity went far toward influencing the modern concep regarding this lesion. His conclusions, based o material obtained at necropsy, unquestionabl are correct so far as his particular series is concerned, but it is impossible to deny the possibl existence of a lesion on the basis of one individual's experience only.

The modern teaching, in brief, states that th presence of evidence indicative of mitral endocarditis invariably warrants the diagnosis of mitral stenosis.

The average normal mitral orifice in adult lif has a circumference of 10 cm. From time t time cases are observed, in which, in life, objective signs justifying the diagnosis of mitral stenosis are not revealed and in which, at necropsy narrowing of the mitral orifice or stenotic fusio of the valve leaflets are not seen, but clear-cu deformity of leaflets exists, permitting varyin degrees of mitral insufficiency to occur.

Furthermore, as shown by Bass and other the rheumatic endocarditis of children is frequently unattended by demonstrable mitral stenosis. Bass, in fact, believes that at least a thir of the cases of mitral insufficiency in childhoo are not complicated by stenosis. It is probabl that most cases of mitral endocarditis are firs brought into evidence by the manifestations o mitral insufficiency, the stenotic process occurring coincidently, or later, as the case may b

It seems desirable, after analyzing the actua facts at hand, to pursue a middle path regardin the diagnosis of pure mitral insufficiency. Its occurrence in adults is admittedly rare, but that i occurs occasionally cannot be contradicted, an its rather frequent occurrence in childhood is fact.

Frederick A. Willius.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

MINNEAPOLIS MIDWIFE PLEADS GUILTY TO VIOLATING BASIC SCIENCE LAW

State of Minnesota *vs.* Marska, alias Mars

On July 8, 1931, Emma Marska, alias Emma Mârs,
tered a plea of guilty to violating the Basic Science
aw. The complaint was filed by Mr. Brist, repre-
nting the State Board of Medical Examiners. Mrs.
arska had her place of business at 246 West Broad-
ay, Minneapolis. She specialized in ailments of
omen, her knowledge having been obtained in Russia
here she was a midwife and where she claimed her
sband was a physician.

Judge Leary of the District Court sentenced the de-
ndant to six months in the Minneapolis workhouse.
he sentence was suspended on the one condition that
e defendant absolutely refrain from practicing heal-
g in this state in the future. The Medical Board has
d this case re-checked since the above date and no
idence of law violation has been discovered.

The Medical Board reports the usual good coöpera-
n from the Hennepin County Attorney's office as
ell as very fair consideration from Judge Leary of
e District bench.

TRUTH ABOUT MEDICINES

Alpha Naphthol Campor Oil (Carel).—It contains
ha-naphthol (New and Nonofficial Remedies, 1931, p.
2), 0.5 Gm.; camphor, 0.5 Gm.; cottonseed oil, 12
n.; liquid petrolatum to make 100 Gm. Carel Labora-
ries, Redondo, Calif.

Alpha-Naphco Camphco Camphor Nasal Unguent.—It
ntains alpha-naphco (New and Nonofficial Remedies,
31, p. 293), 2 Gm.; camphor, 2 Gm.; petrolatum to
ke 100 Gm. Carel Laboratories, Redondo, Calif.

Alpha-Naphco Cones.—Each cone weighs 2.65 Gm. and
ntains alpha-naphco (New and Nonofficial Remedies,
31, p. 293) Gm., in a base composed of boric acid
d sodium bicarbonate, equal parts. Carel Labora-
ries, Redondo, Calif.

Alpha-Naphco Menthol Suppositories.—Each suppository weighs 5.2 Gm. and contains alpha-naphco (New and Nonofficial Remedies, 1931, p. 293), 0.356 Gm., and menthol, 0.014 Gm., in a base composed of oil of theobroma and yellow wax. Carel Laboratories, Redondo, Calif.

Alpha-Naphco Rectal Suppositories.—Each suppository weighs 2 Gm. and contains alpha-naphco (New and Nonofficial Remedies, 1931, p. 293), 0.1376 Gm. in a base composed of oil of theobroma and yellow wax. Carel Laboratories, Redondo, Calif.

Alpha-Naphco Zinc Stearate Camphor Ointment.—It contains alpha-naphco (New and Nonofficial Remedies, 1931, p. 293), 7.5 Gm.; camphor 1.5 Gm.; zinc stearate, 10 Gm.; starch 10 Gm., petrolatum to make 100 Gm. Carel Laboratories, Redondo, Calif.

Alpha-Naphco Zinc Stearate Powder.—It contains alpha-naphco (New and Nonofficial Remedies, 1931, p. 293), 3.65 Gm.; zinc stearate, 8.75 Gm., talcum to make 100 Gm. Carel Laboratories, Redondo, Calif. (Jour. A. M. A., July 11, 1931, p. 103.)

Liver Extract-Lederle.—A concentrated, water soluble, nitrogenous, nonprotein fraction obtained from fresh mammalian liver. It is supplied in vials containing an amount of powdered extract representing approximately 100 Gm. of fresh, whole liver. The product is proposed for use in the treatment of pernicious anemia and tropical sprue. Lederle Laboratories, Inc., Pearl River, N. Y.

Rabies Vaccine (Hixson).—An antirabic vaccine (New and Non-official Remedies, 1931, p. 358) prepared according to the general method of David Semple (phenol killed). The product is marketed in packages of seven vials, in packages of fourteen vials and in packages of fourteen syringes. (Jour. A. M. A., July 18, 1931, p. 179.)

FOODS

The following products have been accepted by the Committee of Foods of the Council on Pharmacy and Chemistry of the American Medical Association for inclusion in Accepted Foods:

Vitamin D Bond Bread (General Baking Co., New York City).—A white bread prepared by the straight dough process containing an added special nutrient vitamin D equivalent to that of three teaspoonfuls of standard cod liver oil for each 24 ounces of baked bread (140 vitamin D units as defined by the Council on Pharmacy and Chemistry). This bread is an adequate food source of vitamin D for normal nutrition.

Lactogen (Nestle's Milk Products, Inc., New York).—A spray-dried modified cow's milk containing added milk-fat and lactose. The prescribed dilution approximates human milk in percentages of milk-fat, protein, lactose and total minerals and in dispersion of the fat in fine globules. Lactogen is intended for infant feeding.

Uffelmann's Golden Krust Bread (The Uffelmann Baking Co., Cincinnati).—A white bread made by the sponge dough method. It is claimed to be a bread of good quality. (Jour. A. M. A., July 4, 1931, p. 31)

« A PAGE FORUM OF THE COMMITTEE ON PUBLIC HEALTH EDUCATION »

Social Workers Take Their Hurdles Easily

Economists, both medical and otherwise, may shy and balk. But the delegates to the National Conference of Social Work held at Minneapolis last June, leaped such barriers as State Medicine, for instance, with the greatest ease and jauntiness. And for platform purposes at least they landed safely on the other side.

"All agreed" says a report on the health section meetings of the Conference by Robert W. Kelso of St. Louis, Chairman, "THAT THERE IS NOTHING SACRED ABOUT THE ANCIENT PRACTISE OF PRIVATE SERVICE FOR PRIVATE FEES; that centralized medical service could be rendered on reduced costs to the individual and with more educational effect."

There were other medical matters on which all at this conference were quite as easily agreed. They should be of sufficient interest to the members of the medical profession who are in fact still engaged in the ancient system of private practise for private fees to warrant quoting below.

It should be noted that Mr. Kelso himself is Director of the St. Louis Community Chest. He and most of the other delegates to the Conference deal constantly in one way or another with the problems of looking after the sick and are in fact more than normally concerned in all problems related to the cost of medical care and its extension. The Committee holds no brief for the following, but quotes it as indicative of the social service workers standpoint.

The final session of the division on Health considered the clinic and dispensary movement; first its history and trends; and second an impartial review of the riddle of state medicine. There are those who profess to fear the dispensary movement; not so with the group gathered in Division III. Reviewing recent calculations upon the mounting costs of medical care, the dispensary was hailed as the probable way out of a growing dilemma. Admittedly some go to the dispensary who could afford to pay a private physician, but it was felt that the physician himself is on the defensive to prove that his method of service with private fees is any better or more ethical for the individual than the group of clinics embodied in the dispensary.

On the score of state medicine the usual criticism was raised that the physician was being left out but it was maintained that if the welfare of the public demanded that the physician should group his specialized services in dispensaries, then this should be done: that there is nothing sacred about the ancient process of private service for private fees. All agreed that centralized medical service could be rendered on reduced costs to the individual and with more of an educational effect.

This spirited discussion dealt impatiently with old methods merely because they were old, and insisted that the conditions of modern life demand the best methods regardless of precedent. It may be said that this attitude was the temper of all the sessions of the Division. In no session of Division III was the floor discussion less than one hour in length."

OF GENERAL INTEREST

Dr. Joseph F. Schaefer, formerly of the Mayo Clinic, Rochester, Minnesota, is now located at Owatonna, Minnesota.

Dr. Lewis M. Daniel of Minneapolis left in July for a trip through France, Germany, and Switzerland. Dr. Daniel will return to Minneapolis about September 15.

Dr. Arthur Edward Smith of Minneapolis sailed August 5 for Vienna where he will spend a month in study. Dr. Smith expects to return to his practice about September 22.

Dr. Carl O. Rice and family, of Minneapolis, left August 10 for Europe. Dr. Rice will study for several months as a fellow at the Surgical Clinic, University of Berne, Berne, Switzerland.

TRAINING SCHOOL FOR MEDICAL RESERVE OFFICERS

The third annual Inactive Training School for Medical Reserve Officers will be held at Rochester, Minnesota, October 18 to November 1 under the auspices of the Mayo Foundation. The course is under the direction of Col. Geo. A. Skinner, Surgeon Seventh Corps Area, and is designed to maintain efficiency of Reserve Officers in their present grades or to prepare them for promotion to the next higher grade.

Medical officers contemplating taking the course should apply at once through their respective corp area headquarters.

L. B. Wilson, *Col. Aux. Res.*

FRAUDULENT COLLECTION AGENCY

Another fraudulent collection agency is reported to be operating in Aitkin, Minnesota, under the name, "The United States Commercial Adjustment Company of Chicago."

This company, so-called, got hold of the list of debtors of an Aitkin physician and sent the entire list threatening letters without any warrant or authority from the physician himself.

The probability is that this agency will attempt to work the same trick throughout the territory and all physicians should be duly warned and on the lookout.

Complaints of unreliable and unethical collection agencies come to the attention of the Secretary of the Minnesota State Medical Association very frequently. It should be a rule for all physicians never to select a collection agency or give any information concerning their accounts without expert advice. In every city and every town there is a banker who can give expert advice. Everybody, including doctors, should think of bankers and go to them about financial matters just as the latter go to the doctor when they are sick.

WARNING

W. A. Oyler, lately of Iowa and Illinois and Indiana, and professedly a Doctor of Medicine, has left Des Moines by order of the police and may be headed toward Minnesota or Kansas or some other nearby state, according to letters received in this office from Robert L. Parker, M.D., Secretary of the Iowa State Medical Society and Harold M. Camp, M.D., Secretary of the Illinois State Medical Society.

This new medical beggar left Indiana some time ago with the funds of a number of sympathetic physicians wrung from them by some tale of hard luck. His next stop was Cicero, Illinois, where his stories roused the suspicions of Dr. Camp, and resulted in an investigation by Dr. Arthur J. Cramp, Director of the Bureau of Investigation of the American Medical Association. The fraudulent record thus unearthed was sent on ahead of the traveller to Iowa and resulted in his arrest in Des Moines.

He is now at large, however, and all physicians are warned to call the County or State Medical Association headquarters, and above all, to refuse aid if any such man should apply to them.

ASTHMOL AND ASTHMOL-EPHERDRINE NOT ACCEPTABLE FOR N. N. R.

Asthmol and Asthmol-Epherdrine are products of Opotherapeutic Laboratory, Sagone & Co., Palermo, Italy, distributed in the United States by the Asthmol Co., New York. Asthmol is a liquid preparation, marketed in the form of ampoules. The product is stated to be a combination of pituitary and suprarenal extracts but no definite statement of composition or potency is made. As the name suggests, Asthmol is proposed for the treatment of asthma. Asthmol-Ephedrine (also referred to as "Syrup of Asthmol") is stated to be composed of: "Ephedrin 0.20 Sodium Benzoate, iodide and bromide, ana 0.25,—Grindelia, 1.75—In 100 c.c. of gomenolo-balsamic syrup. Contains alcohol: 2 per cent by volume." The claims advanced for Asthmol-Ephedrine are typical of those made for complex mixtures—the praise of each constituent is sung without any consideration being given to the question as to whether the several constituents, even if they have the virtues ascribed to them, are indicated at one and the same time and in precisely the amount furnished by the formula. The Council on Pharmacy and Chemistry finds Asthmol and Asthmol-Ephedrine (Dr. Sagone's Syrup of Asthmol) unacceptable for New and Non-official Remedies because their composition is unscientific and indefinite, because their names are therapeutically suggestive and not descriptive of composition, and because the therapeutic claims made for them are unwarranted. (Jour. A. M. A., July 11, 1931, p. 103.)

CONSULTATION BUREAU

Wm. A. O'Brien, M.D., *Director*
Minnesota State Medical Association
11 West Summit Avenue
Saint Paul, Minnesota

1. *Question.*—I have under treatment at the present time an eleven year old girl, who was perfectly well up to July 1st of this year. At that time, she developed generalized hemorrhages in the skin over the entire body. The lesions were first noted on the thighs, but in two days had spread. She also had a slight nose bleed which became more severe and hemorrhages into the tongue which interfered with eating. The fifth day of the bleeding she noticed gross blood in the stool and marked hematuria. Aside from these hemorrhages she has felt fairly well except for headaches.

Physical examination shows a well nourished and developed child. Pulse 102, temperature 99.6, blood pressure 120/76. The hemorrhages in the skin varied from pin point spots to large blotches. The change is most marked on the extremities. Multiple petechia are seen throughout the oral cavity, and blood blisters are present on the tongue and left great toe. The nose shows evidence of recent bleeding. The lymph nodes are not enlarged, neither is the spleen. The tonsils are out. The heart and lungs, and the rest of the physical examination yield no positive findings.

Hemoglobin 75 per cent, erythrocytes 4,440,000, leukocytes 7,250. Differential count—polymorphonuclear neutrophiles 41 per cent, small lymphocytes 55 per cent, large lymphocytes 4 per cent. Platelets greatly diminished. No abnormal red or white blood cells. Coagulation time 7 minutes. Two days later the blood examination was practically the same except that the bleeding time was 5 minutes. The ninth day of the illness, the bleeding time was 3 minutes and the coagulation time 4 minutes. No platelets are seen on the smear.

For the past two days she has been improving. The hemorrhagic spots are fading, but the urine still shows gross blood. Treatment to date has consisted of calcium gluconate by mouth, oral fibrogen, styptysate, and sodium cacodylate. Transfusion has been considered.

I would greatly appreciate suggestions as to the probable diagnosis, treatment, and prognosis.

Answer.—From your description, two conditions will have to be considered: Toxic purpura and thrombocytopenic purpura. The bleeding and coagulation time seem to fall within normal limits. If thrombocytopenic purpura is present, the bleeding time is usually prolonged. The most likely diagnosis is toxic purpura, although the other form cannot be ruled out. Several cases similar to yours have come to our attention. Some of them apparently started as an upper respiratory infection. They have been treated by giving liver extract. A child of eleven should receive about six vials a day. All of our cases have apparently responded to this type of treatment, although one cannot be sure that a natural remission, independent of therapy, did not take place. If the condition is due to a disturbance of the platelets, transfusion may be necessary, if bleeding continues. This type tends to recur and become chronic. The child should be watched from this view point, and if a definite diagnosis of thrombocytopenic purpura can be established, splenectomy is indicated at a later date. Recent reports indicate that about 80 per cent of the cases of true platelet purpura are benefited by this treatment. It is not recommended in the acute types. In addition to the liver extract, your patient should also have a high chlorophyl diet and calcium continued. The outlook is apparently good in your case, but many of these patients do not survive the acute form of purpura, especially the toxic variety.

2. *Question.*—Reports have come to me that there is some serum being used in the chronic stage of Parkinson's disease, and that the results are even better than with hyoscine. If there is any new preparation, I should appreciate hearing about it.

Answer.—The usual treatment of this condition is the use of hyoscine or stramonium. It appears at times as if hyoscine resistent cases respond to stramonium and vice versa. Stramonium may be given in the form of the tincture or the leaves. If the tincture is used, start with 15 minims three times a day after meals; increase the dosage two or three minims at a time until tolerance is reached. This usually occurs at sixty to seventy-fine minims. A typical reaction is usually dry mouth, dilated pupils, and a general feeling of uneasiness. We assume from your letter that you are familiar with the hyoscine treatment.

Serum has not been extensively used although reports in the literature indicate that Coley's serum has been tried. As most people believe that the chief effect of this preparation is due to foreign protein, typhoid vaccine or boiled milk injections may be used. The results of any form of treatment are variable and it is difficult to state what may be expected in a given case. The technique of milk injections was published in the last issue of Minnesota Medicine, XIV, 748, (Aug.) 1931.

3. *Question.*—Is there any contraindication to complete surgical removal of the nipple in a woman past middle life whom I believe has Paget's disease of the nipple? The breast and axilla are entirely negative. Duration is one year. Lesion does not extend beyond the nipple. The biopsy would be sent in at once for microscopic diagnosis. If Paget's disease is present, would deep therapy be the treatment of choice, or should a radical breast amputation be done as soon as the diagnosis is confirmed?

Answer.—Although some authors insist that a preliminary treatment of soap and water should be tried on border line eczematous lesions of the areola, the best method of handling them is to excise the nipple and areola, extending the line of incision well beyond the involved part. If Paget's disease is present, a radical breast amputation, followed by deep X-ray therapy, is the treatment of choice. There are two theories as to the cause of this condition: One, that it is a change in the surface due to disturbance of lymph drainage by carcinoma beneath, and the other that it is a primary malignant degeneration of the nipple and areola. The involvement of the breast and axilla may not be obvious for some time after a simple excision is done. In our experience, many of these cases show a definite tumor later in their course. This is the reason for the recommendation of the usual treatment of malignant disease of the breast for these cases.

OBITUARY

DR. JOSEPH J. McKINNON
1863-1931

Dr. J. J. McKinnon, for thirty-seven years active in the business and social life of Wadena, Minn., died at his home, of arterio-sclerosis, Friday, July 31, 1931.

Of Scotch descent Dr. McKinnon, son of Mr. and Mrs. Laughlin McKinnon, was born in Alexandria, Ontario, Canada, July 22, 1863. He received his early education at the Christian Brothers school and Holy Cross college at Montreal. Possessed of great talent and energy he completed his classical course with honors and took a degree of Bachelor of Arts at Laval University in Quebec in 1884. He spent the next two years as a professor in one of the Catholic institutions in Montreal.

In 1886 he came west and settled for a time at Hudson, Wisconsin, where he engaged in the study of law. Two years later, becoming interested in medicine, he matriculated in the College of Medicine at the University of Minnesota. During his medical course he also taught in the Cathedral school at St. Paul under Bishop Ireland and later became assistant supervisor of Public Night Schools in St. Paul. In this way he paid for his medical education. He was graduated from the university in 1893, and came to Wadena in December of that year.

He returned to Minneapolis for his bride, Miss Anna Blodgett, whom he married September 19, 1894. Dr. and Mrs. McKinnon returned to Wadena where they have since lived. Five children were born to Dr. and Mrs. McKinnon: Mona K., Jerome E., Donald F. and Patricia J. of Wadena and Dr. Laughlin W. of Frazee.

Dr. McKinnon possessed an optimistic and fearless outlook on life and was a man with the courage of his convictions. He was never so happy as when he was using his rugged intellect in a cause which he thought was right. His honesty and courage were widely known and respected and, combined with other admirable characteristics, made his an attractive personalty.

Shortly after his arrival in Wadena he became actively interested in public affairs and served as mayor of the village. He was one of the prime movers in securing the Fair Oaks Lodge sanatorium for Wadena and served as president of the board from the time of its organization until his retirement from public life in 1929. He also administered the affairs of that institution as superintendent from 1925 until 1929.

Likewise he was a strong supporter of the Wesley hospital and served as president of the hospital board after that institution was secured for Wadena. In addition to these offices and the responsibility of a large private practice, he served long terms as county coroner and as city health officer.

Dr. McKinnon considered his profession as a consecrated calling and enjoyed high rank among his professional friends. At various times he held offices in the Minnesota Medical Association and the Upper Mississippi Valley Medical Association. In his years of service as a general practitioner he gave unstintingly of his knowledge, skill, understanding and sympathy.

Dr. McKinnon is survived by his widow, his five children; two sisters, Rev. Sister St. Eusebia, St. Laurent, Ontario, Canada, and Mrs. J. M. MacDonald, Cornwall, Ontario, Canada; and two brothers, Charles of River Falls, Wisconsin and George of Alexandria, Ontario, Canada.

VAPEX

Vapex is manufactured by Thomas Kerfoot and Company, Ltd., England, and is distributed in the United States by E. Fougera and Co., Inc., New York. The stuff is sold at a price that seems to be enormously in excess of the cost of its ingredients, which may explain the vast sums that have been spent on persuading the public that the product is a marvel of therapeutic efficiency. Some of the advertising slogans have been: "Vapex Amazed Scientists . . . Its vapor kills cold germs." "Instant relief for nasal affections with its delightful vapor." An advertisement in *Good Housekeeping* contains the preposterous statement to the effect that "relief from head colds is instantaneous with Vapex." Vapex was examined in the A. M. A. Chemical Laboratory and as a result of this examination the Laboratory concluded that a solution having essentially similar chemical and physical attributes as Vapex may be made as follows: Menthol 15 Gm., Oil of Lavender Flowers 15 c.c., Alcohol 94 per cent to make 100 c.c. It thus appears that this alleged "important medical discovery" is essentially menthol dissolved in alcohol and perfumed with oil of lavender! And it is sold with the implied claim that it will cure nasal infections, give quick relief from catarrh and hay fever, and prevent influenza! (Jour. A. M. A., July 18, 1931, p. 196.)

FAYRO

The Federal Trade Commission has issued a Cease and Desist order against the Fayro Laboratories, Inc., which demands that the unwarranted and false claims made in the exploitation of the "obesity cure" Fayro be discontinued. The Commission found that Fayro had essentially the following composition: Epsom salt, 7½ parts, Common salt, 1½ parts, Glauber's salts 1 part, scented with oil of pine needles. The retail price of Fayro was one dollar; the approximate cost of the ingredients was less than three cents. The exploiters of Fayro advertised that when dissolved in a tub containing a quantity of hot water and the body immersed therein, it would dissolve and remove excess fat. Over one and one-half million packages of Fayro have been sold to the gullible and about one-half million dollars spent in advertising this humbug. When the Federal Trade Commission was holding its hearings, the Fayro concern was able to produce two supposedly reputable physicians, Dr. R. C. Falconer and Dr. William C. Olson, to testify in favor of the nostrum. (Jour. A. M. A., July 11, 1931, p. 122.)

REPORTS AND ANNOUNCEMENTS OF SOCIETIES

MEDICAL BROADCAST FOR THE MONTH

The Minnesota State Medical Association
Morning Health Service

The Minnesota State Medical Association broadcasts weekly at 11:15 o'clock every Wednesday morning over Station WCCO, Minneapolis and Saint Paul (810 kilocycles or 370.2 meters).

Speaker: William A. O'Brien, M.D., Associate Professor of Pathology and Preventive Medicine, Medical School, University of Minnesota.

The program for the month of September will be as follows:

September 2—Lockjaw Prevention.
September 9—Peptic Ulcer.
September 16—Nutrition Education in Our Schools.
September 23—Bichloride of Mercury Poisoning.
September 30—Hodgkin's Disease.

NORTHERN MINNESOTA MEDICAL ASSOCIATION

The following is a tentative program of the meeting of the Northern Minnesota Medical Association which is to be held at Hibbing, Minnesota, on September 14, 1931:

8:30 Clinico-Pathological Conference
Specimens furnished through the courtesy of St. Lukes and St. Mary's Hospitals, Duluth, Minn.
Case presentations by Dr. M. M. Fischer, Duluth.
Pathological reports and specimen demonstration by Dr. George L. Berdez, Duluth.
X-Ray film discussions by Dr. Thos. Gage Clement and Dr. J. R. McNutt, of Duluth.
Discussions led by Dr. E. L. Tuohy, Duluth.
9:30 Ectopic Pregnancy—Drs. R. L. Bowen and T. A. Estrem, Hibbing.
9:50 Multiple Sclerosis—Dr. L. R. Gowan, Duluth.
10:10—Fractures of Tibia and Fibula, Involving the Joints—Dr. C. W. More, Eveleth.
10:30 Pediatric Subject—Dr. O. W. Rowe, Duluth.

INTERMISSION 15 MINUTES

11:05 Common Pathology of the New Born—Dr. Thomas Myers, St. Paul.
11:25 Pathology of Peptic Ulcer—Dr. D. C. Collins, Rochester.

LUNCH

Trip on observation car into Hull-Rust Mine. (Leave Androy Hotel in autobomiles for the mine at 12:45)
2:30 Modern Anesthesia—Dr. J. S. Lundy, Rochester.
2:50 Title unannounced—Drs. R. B. Bray and W. H. Long, Fargo, North Dakota.
3:10 Remote Effects of Head Injuries—Dr. W. H. Hengstler, St. Paul
3:30 Comparison of Number of Physicians in Different Sections of the United States, and also Europe—Dr. N. O. Pearce, Minneapolis.
4:00 What the American Doctor Sees in Europe—Dr. A. M. Snell, Rochester.
BANQUET at 6:30 or 7:00 P. M.—Drs. M. S. Henderson, E. A. Meyerding, and Mr. Mackey.

MISSISSIPPI VALLEY CONFERENCE ON TUBERCULOSIS AND SANATORIUM ASSOCIATION

The joint yearly meeting of the Mississippi Valley Conference on Tuberculosis and the Mississippi Valley Sanatorium Association will be held this year at the Lowry Hotel in St. Paul, September 21, 22 and 23.

This double conference gathers together medical experts in tuberculosis, public health and social workers interested in the anti-tuberculosis movement from 12 Mississippi valley states. Three days of intensive study on medical and medico-sociological subjects and on Christmas Seal organization characterizes the program.

Among the states participating are Illinois, Iowa, Kansas, Michigan, Minnesota, Missouri, Nebraska, North Dakota, South Dakota, Ohio and Wisconsin.

This year's program, in the hands of J. W. Becker, St. Louis, program chairman and of Walter J. Marcley, M.D., director of the tuberculosis division, U. S. Veteran's Hospital, Fort Snelling, president of the conference, and E. A. Meyerding, M.D., executive secretary of the Minnesota State Medical Association and secretary of the conference, promises to be outstanding among the 18 previous gatherings of the organization's history.

Tuberculin testing in all its aspects; case finding, vital statistics; the problem of tuberculosis in adolescence and the problem of the under-par child all will have consideration at various sessions.

Following is the tentative program of the sanatorium association session:

TENTATIVE PROGRAM
SANATORIUM SECTION MEETING
MISSISSIPPI VALLEY CONFERENCE ON TUBERCULOSIS

Hotel Lowry, St. Paul
September 21 and 22, 1931

Monday, September 21, 9:30 A. M.
Dr. E. R. Van Der Slice, Presiding

9:30 A. M.—Tuberculin Testing by Districts in Minnesota—Dr. W. S. Broker, Otter Tail County Sanatorium, Battle Lake, Minn.
Discussion (10 min.)—Dr. Mary C. Ghostley, Lake Julia Sanatorium, Puposky, Minn.
10:00 A. M.—Phrenico-Exeresis in the Treatment of Lung Disease—Dr. Jerome R. Head, Chicago, Ill.
Discussion.
10:30 A. M.—Increasing Importance of Silicosis—Dr. A. W. Gray, Milwaukee, Wis.
Dicussion.
11:00 A. M.—X-ray Clinic (To demonstrate the value of serial X-ray films in determining the progress of tuberculosis)—

(A) Dr. G. D. Kettelkamp, Robert Koch Hospital, Koch, Mo.
(B) Dr. C. F. Taylor, Kansas State Sanatorium, Norton, Kan.
(C) Dr. Paul D. Crimm, Boehne Hospital, Evansville, Ind.
(D) Dr. W. M. Spears, Oakdale, Ia.

Monday, September 21—2 P. M.
Dr. F. L. Jennings, Presiding

2:00 P. M.—Spontaneous Pneumothorax—Dr. Max Biesenthal, Chicago, Ill.
Discussion.

2:30 P. M.—Endoscopy in the Diagnosis and Treatment of Non-Tuberculous Diseases of the Lungs (Lantern)—Dr. Wm. A. Hudson, Detroit, Mich.
Discussion.

3.00 P. M.—Conservative vs. Surgical Treatment of Bone Tuberculosis—
Conservative Treatment—Dr. Robinson Bosworth, Municipal Tuberculosis Sanatorium, Rockford, Ill.
Surgical Treatment—Dr. Melvin Henderson, Mayo Clinic, Rochester, Minn.
Discussion.

:00 P. M.—(A) What the X-ray Shows in Tuberculin Reactors—Dr. L. G. Rigler, University Hospital, Minneapolis, Minn.
(B) Types of Lesions Noted—Dr. J. A. Myers, Minneapolis, Minn.
Discussion.

onday, September 21—8 P. M., Glen Lake Sanatorium, Oak Terrace, Minn.
Dr. E. S. Mariette, Presiding

:00 P. M.—Tuberculosis Treatment Plus the Three R's—Dr. David A. Stewart, Associate Professor of Medicine, University of Manitoba, and Superintendent of the Manitoba Sanatorium, Ninette, Manitoba, Canada.

:20 P. M.—The Advantages of Surgical Facilities in a Sanatorium—Dr. Jerome Head, Chicago, Ill.

:40 P. M.—Scope and Possibilities of a Laboratory in a Tuberculosis Sanatorium—Speaker to be determined.

:00 P. M.—Changes in the Last Ten Years Made in the Sanatorium Treatment of Tuberculosis—Dr. Walter J. Marcley, President, Mississippi Valley Conference, and Chief of the Tuberculosis Division of the Veterans' Hospital, Fort Snelling, Minn.

Tuesday, September 22—9:00 A. M.
Dr. Alfred Henry, Presiding

:00 A. M.—The Need for Medical Social Service Work in Sanatoria—Miss Marguerite A. Ridler, Director of Social Service, Glen Lake Sanatorium, Oak Terrace, Minn.
Discussion—Dr. Hoyt E. Dearholt, Executive Secretary, Wisconsin Anti-Tuberculosis Association, Milwaukee, Wis.

9:30 A. M.—Interesting Case Reports (Each case to include a history, complete clinical information, X-ray records and films, autopsy record, macroscopic and microscopic demonstration.)—
(A) Dr. Wm. S. Middleton, Associate Professor of Medicine, University of Wisconsin, Madison, Wis.
(B) Dr. V. V. Norton, Hamilton County Tuberculosis Sanatorium, Cincinnati, Ohio.
(C) Dr. F. L. Jennings, Glen Lake Sanatorium, Oak Terrace, Minn.
(D) Dr. R. H. Morgan, Detroit, Mich.

11:30 A. M.—Tuberculosis in a Rural District—Dr. Edw. J. Simons, Swanville, Minn.
Discussion (5 min.)—Dr. Herman Hilleboe, Swanville, Minn.
(5 min.)—Dr. J. A. Myers, Minneapolis, Minn.

Tuesday, September 22—1:30 P. M.
Dr. E. R. Van Der Slice, Presiding

1:30 P. M.—Principles of Out-Patient Work in a Sanatorium—Dr. Geo. McL. Waldie, Copper County Sanatorium, Houghton, Mich.
Discussion.

1:50 P. M.—Following Up Sanatorium Patients—Dr. Geo. Thomas Palmer, Palmer Sanatorium, Springfield, Ill.

2:15 P. M.—Does Childhood Tuberculosis Require Hospitalization?—
Proponent—Dr. C. L. Hyde, Springfield Lake Sanatorium, East Akron, Ohio.
Opponent—Dr. C. A. Stewart, Associate Professor of Pediatrics, University of Minnesota, Minneapolis, Minn.
Discussion.

3:00 P. M.—Is the Sanatorium a Safe Place for Nurses?—Dr. E. S. Mariette, Glen Lake Sanatorium, Oak Terrace, Minn.
Discussion.

3:30 P. M.—Is a Good History 50 per cent of the Diagnosis in Tuberculosis? (With charts.)—Dr. Oscar Lotz, Wisconsin Anti-Tuberculosis Association, Milwaukee, Wis.
Discussion.

4:00 P. M.—(A) Tuberculin Reaction—What Is It?
(B) Does a Positive Reaction to Tuberculin Mean More Than Infection with Tubercle Bacilli? —Speaker to be determined.
Discussion.

AMERICAN CONGRESS OF PHYSICAL THERAPY

The tenth anniversary session of the American Congress of Physical Therapy will be held October 5, 6, 7, 8, 1931, at the Hotel Fontenelle, Omaha, Nebraska. Appreciating the desirability of clinics and clinical demonstrations, the program committee has set aside the mornings for these purposes. It will be the first time that the society will have available ample clinical material for medical and surgical services. The coöperation of the University of Nebraska College of Medicine and the Creighton University School of Medicine has made this possible. In the section on Eye, Ear, Nose and Throat, tonsil clinics will be conducted daily during the first three days of the meeting. Electrosurgery for tonsils has found a definite place in the armamentarium of many surgeons. Prominent specialists will demonstrate the various methods and technics now being employed.

The subject of fractures will be thoroughly covered in the surgical clinics. Leading orthopedic surgeons will demonstrate every phase of the work, emphasizing the indications and contraindications for physical therapy.

In the medical section and in the medical clinics every allied specialty is represented. The subject of pneumonia will be adequately discussed, as will such subjects as come in the fields of pediatrics, gastroenterology and dermatology. Massage, therapeutic exercise and hydrotherapy will be presented by specialists in those fields.

The scientific papers will be read during the afternoon sessions. The unusually wide range of subjects and the meritorious papers which will be presented make this program an outstanding one.

The progressive physician who is desirous of keeping abreast of the times can no longer neglect his attendance at a meeting such as this one. Physicians desirous of having their technicians and assistants acquaint themselves with the newer developments in physical therapy are invited to have them attend this four-day scientific meeting. For preliminary program and other information write to the American Congress of Physical Therapy, 30 North Michigan Avenue, Chicago, Illinois.

INTER-STATE POST GRADUATE MEDICAL MEETING

The annual International Assembly of the Inter-State Post Graduate Medical Association of North America will be held in Milwaukee October 19 to 23 inclusive.

The preliminary program of morning, afternoon, and evening clinics and addresses contains the names of distinguished physicians and surgeons for the most part professors or associate professors of medical schools in Canada and the United States. The program this year does not include the names of any foreigners. Many names not noted on previous programs appear.

All the specialties in medicine are covered in the subject material and attendance at the services will prove of great value no matter what phase of medicine one may be interested in.

SCOTT-CARVER COUNTY SOCIETY

The annual meeting of the Scott-Carver County Medical Society was held at Shakopee, Minnesota, on Tuesday, June, 9, 1931. Dr. Gardner of St. Paul gave an interesting talk on "Bronchoscopy in the Removal of Foreign Bodies from the Bronchi and Esophagus." Dr. F. E. B. Foley, also of Saint Paul, gave a very comprehensive talk on "Obstructions at the Ureteral-Pelvic Junction." Both talks were illustrated with lantern slides.

The following officers were elected to serve for the year 1932: President, Dr. W. S. Emmerson, Mayer; vice president, Dr. H. M. Juergens, Belle Plaine; secretary-treasurer, Dr. C. F. Cervenka, New Prague; delegate, Dr. H. A. Schneider, Jordan; alternate delegate, Dr. B. H. Simons, Chaska; censor for three years, Dr. H. E. Wunder, Shakopee.

WRIGHT COUNTY SOCIETY

The second quarterly meeting of the Wright County Medical Society was held at Annandale, Minnesota, on Friday, April 10, 1931, at 3:00 o'clock P. M.

Dr. W. A. Fansler, Minneapolis, gave a short talk and a clinical demonstration of the Treatment of Hemorrhoids. A great deal of interest was shown by the local men in this type of treatment.

The other speaker, Dr. R. R. Sullivan, member of the State Board of Health, gave a talk on syphilis and gonorrhea, and illustrated his talk by several reels of moving pictures, illustrating the male urogenital anatomy—when normal and when infected. His talk aroused a great deal of comment and the various methods of treating venereal diseases were discussed pro and con. It was brought out very clearly that the usual method of treating gonorrhea is detrimental to the patient. It was also brought out that the gonoccocus vaccine is only useful as a provocative and has no place as a curative.

This was one of the most interesting meetings ever held, and a larger attendance than we have had for some time.

The following were visitors: Drs. K. A. Walfred, Cold Springs, Minn.; R. N. Jones, St. Cloud, Minn.; Dr. Olsen, Cokato, Minnesota, and Dr. A. Ridgway, South Haven, Minn.

A short business meeting was held in which Dr. L. Bendix' application to membership was accepted.

C. L. Roholt, M.D., *Secretary.*

MINNESOTA MEDICAL ALUMNI ASSOCIATION HOMECOMING PROGRAM

A Homecoming Program similar to the one so successfully given two years ago by the Minnesota Medical Alumni Association will be given this year, on October 30, the day preceding the Homecoming football event

The complete program will appear in our October number. The tentative program includes the following

Dr. E. Starr Judd, President of the American Medical Association: "The Present Status of Surgery of the Gallbladder."

Dr. S. Marx White, President of the American College of Physicians: "Unimportant Heart Murmurs."

Dr. T. J. Kinsella: "Thoracic Surgery."

Other speakers will be: Dr. Irvine McQuarrie, Dr. John Butler, Dr. C. Nauman McCloud, Dr. J. M. Hayes, Dr. J. R. Aurelius, Dr. R. E. Scammon, Dr. J. C. McKinley.

The business meeting of the Alumni Association will be held at noon, at which time the Millard Memorial will be dedicated.

The program should attract as large an attendance as two years ago.

Dr. James S. Carey, 1009 Nicollet Avenue, Minneapolis, is Chairman of the Executive Committee.

WOMEN'S AUXILIARY
Minnesota State Medical Association

President—Mrs. James Blake, Hopkins
Chairman Press and Publicity—Mrs. W. A. Lee, Fergus Falls
Editor—Mrs. Horatio B. Sweetser, Jr., Minneapolis

The Auxiliary to the Minnesota State Medical Association is swinging into the work of a new year under the leadership of Mrs. James Blake of Hopkins, and the newly elected officers and committee chairmen of departments of work appointed by Mrs. Blake.

There are twenty-three Auxiliaries covering fifty-four counties. The county presidents are: Blue Earth, Mrs. A. E. Sohmer, Mankato; Camp Release, Mrs. J. S. Kilbride, Canby; Hennepin County, Mrs. Martin Nordland, Robbinsdale; McLeod County, Mrs. Thomas J. Trutna, Silver Lake; Meeker County, Mrs. A. W. Robertson, Litchfield; Mower County, Mrs. A. W. Allen, Austin; Nicollet-LeSueur, Mrs. Joseph O. McKeon, Montgomery; Olmsted County, Mrs. M. S. Henderson, Rochester; Park Region, Mrs. C. O. Estrem, Fergus Falls; Ramsey County, Mrs. W. H. Hengstler, St. Paul; Red River Valley, Mrs. B. C. Bernard, Thief River Falls; Redwood-Brown County, Mrs. Wm. A. Meierding, New Ulm; Rice County, Mrs. M. L. Mayland, Faribault; Scott-Carver County, Mrs. B. H. Simons, Chaska; Stearns-Benton, Mrs. Werner Hemstead, St. Cloud; Steele County, Mrs. A. B. Hart, Sr., Owatonna; St. Louis County, Mrs. F. N. Knapp, Duluth; Southwestern Minnesota, Mrs. L. Sogge, Windom; West Central, Mrs. Charles Bolsta, Ortonville; Washington County, Mrs. Wilfred Hewson, Stillwater; Wright County, Mrs. John Catlin, Buffalo.

"The word 'Auxiliary' is defined by the Standard Dictionary as 'giving or furnishing aid or support, especially in a subordinate or secondary manner supplementary accessory,'" says Mrs. Blake. "I take the liberty of presenting this definition because it so well expresses the real objects and purposes of the work of the Auxiliary, and at the same time so definitely states the limitations of our work.

"Joining and taking an active part in the Women's Auxiliary could very well be ranked as the first activity which any physician's wife should assume outside her home. The immediate welfare of physicians and their families and the future of medical practice depend upon what the public thinks and does with regard to medical practice and health activities. Organized medicine exists largely for the scientific advancement of its members, the betterment of the profession, and proper guidance of health activities. Except for scientific education, practically every purpose of organized medicine needs the assistance of a Woman's Auxiliary. The work of our County Auxiliaries runs along three definite lines—educational, social and philanthropic—and many times we find the first and third combined."

The National Convention of the Woman's Auxiliary to the American Medical Association, held in Philadelphia in June proved a success in every way. Over 1,100 women were registered and attended the three general meetings, and State presidents from thirty-seven states gave reports of their activities, social, philanthropic, and educational. The latter proved the most important activity as every one sensed the need of a public educated to the ideals of Organized Medicine. Many states were advocating student loans.

Dr. Joel T. Boone, Mr. Hoover's physician, and Dr. E. Starr Judd spoke at the Woman's Auxiliary luncheon. At a joint meeting with the A. M. A. we heard the address of the new A. M. A. president, Dr. Judd, from our own State.

Members of the Auxiliaries of Pennsylvania, Delaware and New Jersey were hostesses at various places: Valley Forge, Longwood, Atlantic City, Delaware River, historic Philadelphia, and at the President's reception.

Mrs. Walter Jackson Freeman, Convention Chairman, is to be congratulated on the efficiency with which her committee handled the convention, and the comfort and pleasure with which the large number of visitors were entertained during their stay in hospitable Philadelphia.

CAMP RELEASE AUXILIARY

The women's auxiliary to Camp Release Medical Society met at Ramsey Park, Redwood Falls, on Friday, July 31. Mrs. J. S. Kilbride of Canby, President, presided at the business session. It was voted to have a speaker at the next meeting of the Auxiliary. Mrs. H. T. Foshager, Clara City, and Mrs. W. N. Lee, Madison, were named on the Publicity Committee; Mrs. A. B. Mitchell, Hector, and Mrs. Hauge on the Legislative Committee, and Mrs. Cress and Mrs. Duncan on the Public Health Committee.

The following doctors were named by the Camp Release Society as members of the Advisory Board for the Auxiliary: Dr. L. S. Jordon, Granite Falls, Dr. L. G. Smith, Montevideo, and Dr. E. Flynn, Redwood Falls.

A picnic supper was served to the Auxiliary members and the members of Camp Release Medical Society at six o'clock.

SCOTT-CARVER AUXILIARY

Scott-Carver Auxiliary met at Norwood, Wednesday, August 5, with Mrs. E. J. Eklund as the hostess. Mrs. Hesselgrave, Mrs. Schons and Mrs. Blake were guests. Talks of general interest to the group were the feature of the meeting and all enjoyed a delicious lunch. Scott-Carver Auxliary is growing—new members were welcomed by the President, Mrs. Simons of Chaska and the State President, Mrs. Blake.

THE PARK REGION DISTRICT AUXILIARY

The Women's Auxiliary to the Park Region Medical Society met with their husbands July 15, at the Ottertail County Sanatorium where they were entertained at a delicious dinner by Dr. and Mrs. Broker. At the business meeting the following officers were elected: President, Mrs. C. O. Estrem, Fergus Falls; vice president, Mrs. P. Boyeson, Pelican Rapids; treasurer, Mrs. W. S. Broker, Battle Lake; secretary, Mrs. W. A. Lee, Fergus Falls.

WASHINGTON COUNTY AUXILIARY

The Washington County Medical Society and Women's Auxiliary held their annual picnic on Thursday evening, July 9, on the beautiful grounds of Lakeview Memorial Hospital. A picnic basket was packed and sent to one of our honorary members, Mrs. E. E. Wells.

THE INSOLOID (INSUROL) FRAUD

For the past year or two, there has been exploited from New York City and Bridgeport, Conn., a particularly vicious piece of quackery directed against diabetics. The nostrum involved was known, first, as Insurol and was sold by Officinal Products, Inc., of 276 West 43rd St., New York City. The advertising stated that Insurol Tablets "combined insulin with the actual substance of the pancreas gland" and they were described as "a triumph of German's biochemical laboratories." Later, the name of the concern was changed to the Insurol Company of America, Inc. About the time that this change was made, there was also a change in the name of the product from Insurol to Insuloid and the public was told, in effect, that Insuloid was merely a new name of Insurol. The facts were that the products were entirely different. Insurol Tablets were keratin-coated and contained animal tissue (probably derived from the pancreas). They did not contain boldo, jambul, myrtillin, bean-pod tea, or lithium benzoate. Insuloid, on the other hand, was an uncoated tablet and contained all of the products just named, except pancreatin. It did not contain insulin. Government experts introduced uncontroverted testimony to show that neither Insurol tablets nor Insuloid tablets would cure diabetes and that neither was a substitute for insulin administered hypodermically. The Post Office authorities issued a fraud order against the Insurol Company, Inc., H. C. Young, President and Official Products, Inc., Otto Probst, Manager, at New York City and Bridgeport, Conn. (Jour. A. M. A., July 4, 1931, p. 47.)

PROGRESS

Abstracts to be submitted to Section Supervisors.

Members are urged to abstract valuable articles which they run across in their reading and send the abstracts to the physicians in charge of the respective sections. In order to avoid duplication it would be well to communicate with one of the section supervisors before the article is abstracted.

EYE, EAR, NOSE AND THROAT

THE SUPPURATION OF THE PETROUS PYRAMID: Pathology, Symptomatology, and Surgical Treatment: S. J. Kopetzky and Ralph Almour. (Ann. Ophthal., Rhinol and Laryng., Part I—39, Dec., 1930, p. 996; II—40, March, 1931, p. 157; III—40, June, 1931, p. 396). A new clinical entity is described. Experience with otitic and mastoid lesions that have been followed after the usual therapy, by an almost symptomless period—then a terminal meningitis, led the authors to view with a new concern, the symptoms of this quiescent period before the terminal symptoms appeared. The significance of the possibilities of a pneumatized petrous process and the symptoms of extension of infection to this area became evident.

Three avenues of invasion of the petrosa seem probable:

1. From the antrum or epitympanic space above or below the superior semicircular canal following the posterior superior wall of the petrosa into the pyramidal tip. 2. From the peri-tubal cells into the pyramidal tip. 3. From the peri-tubal cells directly into the carotid canal and then rupturing in the cavum meckeli.

The symptoms of petrous tip suppuration are divided into four periods:

I. Period of eye pain and aural discharge.

A persistent pain, orbital in location, must be caused by a lesion in direct proximity to the ophthalmic branch of the fifth nerve, for it has no sensory connection with other nerves in the petrosa. When surgical removal of the purulent focus in a mastoid process and middle ear does not result in the cessation of pain distributed over areas supplied by the second and third branches of the fifth nerve, the persistence of pain should be viewed as suspicious of a petrosal tip suppuration when it is continuous in nature and not of a spasmodic type.

In the authors' cases, either the middle ear continued to discharge until the lesion in the petrous tip was identified and eradicated, or else after the period during which the ear was dry, a profuse discharge suddenly reappeared at the same time as or shortly before the onset of the eye pain. (The authors suggest that explanation is offered of those cases of chronic suppurative otitis media associated with a normally pneumatized mastoid process, wherein the squamous epithelium plays no rôle, either in the cause or cure of the lesion. Wittmaack's work, to which the authors subscribe, explains the chronic otorrhea in cases where the factors of sclerosis and epithelium apply).

Other symptoms during this period were: facial weakness and vertigo and nystagmus in two cases, vomiting in several.

II. The period of low grade sepsis.

The temperature was low in the morning, usually between 99 and 100 degrees; toward late afternoon it would rise to 101 or 102.

III. The period of quiescence.

This averaged in the authors' cases between five and nineteen days. It was characterized by an absence of pain.

IV. The treminal period.

This presents in the main a clinical picture of an acute purulent leptomeningitis.

The information that the laboratory furnishes is negligible. Only the X-ray can be used to decided advantage.

The authors' surgical treatment of petrosal tip suppuration consists of, first, a simple mastoidectomy, then inspection of the area beneath the posterior semicircular canal leading toward the jugular bulb and in the region of the solid angle. An endeavor is made to find the point of invasion which characteristically appears as a fistulous opening with granulations around the mouth. If it is probed, a flow of pus almost always follows. A radical cavity is then completed, and, following the toilet of the middle ear, the inner wall of the antrum and epitympanic space are searched for a fistulous opening leading into the petrosa. The areas to be inspected particularly are the spaces directly in front of and behind the superior semicircular canal. The over-hanging anterior external auditory canal and zygomatic root are removed and the anterior wall thinned down with a burr without opening into the glenoid fossa. The zygomatic root is then further removed to a level with the tegmen tympani. The housing of the tensor tympani muscle is removed. An entrance by burr is then made into the petrous process between the eustachian tube, cochlea, and carotid canal. The line of direction corresponds to a line drawn from the apex to the basal whorl of the cochlea.

PHYSICAL THERAPY IN THE TREATMENT OF DISEASES OF THE EAR, NOSE AND THROAT: T. H. ODENEAL, M.D., Beverly, Mass., (Arch. of Otolaryn., July, 1931, Volume 14, Number 1). In this article the author admits having wasted considerable time in experimenting with physical therapy in practically all the conditions in which these measures have been recommended, and follows by giving his experiences and results.

Diathermy is first taken up, and has been used by him principally in removing superficial growths about the face, and in the coagulation of tonsils. The latter subject is, of course, of considerable interest at the present time, due to the constant propaganda which has appeared in the public press on its behalf. He condemns desiccation of the tonsils as being too tedious and time-consuming to be worthy of attention, but claims that coagulation has given satisfactory results if patiently carried out. It is his custom to coagulate each tonsil on alternate occasions at least six times, and says that the result leaves a throat which appears smooth, and (as far as can be seen) the capsule is destroyed. He says that post-operative bleeding is as a rule very slight, but that on two occasions she has had severe hemorrhages following the separation of the slough, one of which necessitated suturing of the tonsil and pillar.

A warning is given not to mislead patients by telling them that the throat will not be sore after coagulation. If there is no soreness, that treatment has been valueless. Some patients complain bitterly of this soreness, whereas, others state that it is not severe.

In conclusion he states that while he coagulates a great many tonsils, his method of choice is still use of the knife, and this advice he always gives to his patients, unless there is some very valid reason why it cannot be done.

Under a heading of Medical Diathermy, his results would seem to indicate that it is of definite benefit, in certain cases of loss of hearing, as well as exudative types of otitis media. It is not employed by him in chronic suppurative otitis media. In acute rhinitis it seems to be of extinct benefit, as it also is in chronic infections of the ear canal.

Ultraviolet Light. Ultraviolet light seems to arouse very little enthusiasm on the part of the author. He claims it is of no value, whatever, in chronic suppuration of the ear, unless there is a very large perforation through the drum membrane. Neither has he had any permanent result from its use in diseases of the nose and accessory sinuses. The result in hayfever has been practically negative, and this is also true in vasomotor-rhinitis.

However, irradiation of the entire body with the air-cooled lamp seems to be definitely beneficial in cases of sinus disease in children, by reason of its general tonic effect on the body. Care must be used not to overdose the patient.

In Diseases of the Throat, Vincent's Angina, and tubercular-laryngitis, occasionally good results are achieved.

Galvanism is mentioned, and seems to find its best application in the removal of varicosed vessels of the skin of the face. It is also of some value in so-called neuralgia pains.

The Infra-Red Light applied in sinus diseases, especially in acute infections of the frontal sinuses, gives good results in the relief of pain. This he believes, however, to be due principally to the heat generated by the lamp. The same is true in inflammatory conditions of the eye, such as iritis and acute glaucoma.

His experience with the Kinesiphone and audotor, as mechanisms to relieve deafness, has been almost uniformly disappointing.

The whole article gives one the impression of a fair-minded report by a man who has been willing to devote sufficient time and energy to this type of experimentation, and has based his report on first-hand knowledge.

M. W. Wheeler, M.D.

RETROBULBAR OPTIC NEURITIS ORIGINATING IN THE NASAL SINUSES—A new method of demonstrating the relation between the sphenoid sinus and the optic nerve: Harris H. Vail, M.D., Cincinnati, (Arch. of Otolaryngol., June, 1931, Volume 13, Number 6). This worthwhile article is so well summarized by the author, that his summary is being quoted verbatim.

1. A brief résumé of the literature quoted by Canuyt, Ramadier and Velter would seem to show that retrobulbar optic neuritis of nasal origin has been recognized for several centuries.

2. The pathologic studies of Professor Herzog, of Inssbruck, are quoted, and his belief is emphasized that they will explain in every way the mechanism of the production of retrobulbar optic neuritis from posterior nasal sinusitis.

3. Statistics of various authors are quoted to show that the incidence of retrobulbar optic neuritis originating in the nasal sinuses varies according to the particular author's acceptance or denial of a nasal sinus etiology of retrobulbar optic neuritis.

4. A series of fifteen cases of retrobulbar optic neuritis of nasal origin seen by me are tabulated.

5. An important observation is made, namely, that when the onset of blindness was acute and could be definitely dated, it was always noticed after awakening from sleep. The position of the head in sleeping favors the gravitation of infection to the upper outer angle of the sphenoid sinus where the optic nerve is in closest relation.

Table 8.—Final Visual Acuity

	No Operation (6 Cases)		Operation (9 Cases)		
	No Treatment	Recovery Vision 20/25 or Better	Complete Recovery Vision 20/20	Vision 20/30	Slight Improvement; Vision 20/100 or Less
Cases	3*	3	7**	1	1***
Per cent	50	50	77	11.1	11.1

*One of these patients (the recurrent case) would not consent to operation.

**This includes one of the bilateral cases; vision in one eye was 20/20; in the other, 20/100.

***This does not include one of the bilateral cases; vision in one eye was 20/100; in the other eye, 20/20.

6. Statistics are quoted to show that the ocular symptoms constitute an early indication of multiple sclerosis in only 14 per cent of the cases, and the opinion is stressed that the virus of multiple sclerosis may gain entrance to the central nervous system from the sphenoid sinus in the same way that organisms have been shown to do. If this is a fact, it would immediately indicate that an early operation on the posterior sinuses should be performed in cases of multiple sclerosis.

7. A new method is described of roentgen visualization of the relations between the optic canal and the sphenoid sinus by means of filling the sinus with radiopaque oil and so placing the patient's head that the upper outer angle of the sinus is dependent. Thus, the radiopaque oil comes into contact with the boundary of the sphenoid sinus where it is most closely related to the optic nerve. In no other position can this be shown.

Lucian G. Culver, M.D.

THE ROENTGEN FINDINGS IN SUPPURATION OF THE PETROUS APEX: Henry K. Taylor (Ann. Ophthal., Rhinol. and Largng., 40, June 31, p. 367). This presentation is based on the clinical work of Kopetzky and Almour; the roentgen findings were verified at operation.

It is routine now on their service to include in addition to the stereoscopic examination, a base plate and an anterior oblique projection of each petrous pyramid. The two latter are for reference. The author recommends for this examination the use of a fine focus tube, a small or medium sized cone, intensifying screens, and the Potter-Bucky diaphragm.

Position for the base plate: The patient is supine, with head lower than the remainder of the body and rests on the vertex, so that a line drawn through the auditory meatus and superior orbital margin is parallel to the table. The sagittal plane of the head is perpendicular to the table; the plate is horizontal. The tube is tilted upward 15 to 20 degrees, so that the central ray is in the midline, one inch in front of the auditory meatus.

Position for the anteroposterior oblique projection of the pyramid: The patient is supine and the head rotated 45 degrees to the side opposite the one to be radiographed. The chin is pulled in. The film is horizontal. The central ray is perpendicular to the film and passes through a point one inch above the external angle of the uppermost orbit.

Interpretation: There is a slight diminution in aeration of a pneumatized petrosa in the presence of an acute otitis media or mastoiditis. One of the earliest findings in petrosal tip suppuration is a marked diminution in aeration with loss of trabeculations followed by decalcification or atrophy of the apical portion, the contour of the apex remaining intact. With progression, there is perforation and destruction of the contour of the apex.

Lawrence R. Boies.

MEDICINE

TUBERCULOSIS ABSTRACTS*

Atelectasis is defined as imperfect expansion of the lung. The condition is usually considered to be due to a gross obstruction in, or compression of, one of the larger bronchi, which prevents the expansion of the distal alveoli and causes their collapse. Several recent articles point out that atelectasis is a frequent occurrence in pulmonary tuberculosis and that it accounts for many of the physical and X-ray signs usually attributed to the tuberculous lesions. An understanding of the mechanism of atelectasis in pulmonary tuberculosis helps to clear up many of the puzzling phenomena of physical signs which cannot logically be accounted for by the existing pathology.

Atelectasis in Pulmonary Tuberculosis

Atelectasis in pulmonary tuberculosis may be caused in a number of ways. Tubercle bacilli commonly lodge in the terminal bronchioles where ciliated epithelium is not present and there tubercles are most likely to develop. The alveoli, or air cells, distal to the terminal bronchioles collapse and eventually become indurated. Large bronchi are also frequently invaded by the tuberculous process and produce atelectic areas distally. Extensive atelectasis is of common occurrence in chronic, fibroid tuberculosis, due to occlusion of bronchi by scar tissue or caseous material. Large tuberculous lymph nodes may, by pressure on the trachea or bronchi, cause patches or even extensive masses of atelectasis.

Apart from bronchial occlusion, there are other factors which favor atelectasis. In tuberculous lesions, particularly cavities, the air exchange is poor and the air pressure in cavities may be greater than the atmospheric pressure. Lobules supplied by bronchi intercepted by such cavities are likely to be collapsed. Atelectasis is probably favored also by the methods of treating tuberculosis; extended rest in bed, breathing with little effort, avoiding cough.

X-RAY SIGNS OF ATELECTASIS

A characteristic anatomical finding in pulmonary tuberculosis is the small lung with elevated diaphragm and displacement of the mediastinum to the affected side. The diminution in size of the lung and the visceral displacement are not caused by contracting fibrous adhesions, for these changes are frequently observed early in the process before adhesions of any extent could form. Moreover, these findings also occur in types of tuberculosis that are not usually associated with fibrosis (miliary and pneumonic).

Bushnell finds displacement of the heart a very early sign and a delicate index of the existence of disease of the lungs. Norris finds a decrease in size of the entire hemithorax in unilateral, early tuberculosis. By fluoroscopic examination of cases with unilateral tuberculosis, the mediastinum is seen to move pendulum-wise toward the affected side during deep inspiration and back to the normal side during forced expiration. These and other observations indicate that the contracted lung of tuberculosis and visceral displacement are not always due to adhesions but are more often a manifestation of airlessness of the affected lung.

PHYSICAL SIGNS OF ATELECTASIS

Contraction of the affected side and restricted mobility are observed by mensuration and by inspection in early cases of tuberculosis. By percussion can be demonstrated signs of contraction of the entire lung, elevation and small excursions of the diaphragm. The earliest findings by auscultation are impairment or absence of the vesicular murmur and the gradual establishment of the bronchial murmur. Atelectasis accounts for or explains these changed breath sounds.

In more advanced lesions, physical signs become more pronounced; râles appear, and the mediastinal displacement comes into evidence. One of the most important signs in tuberculosis is the finding of râles during inspiration immediately following the expiratory cough. Such râles are due to the opening and closing of collapsed air passages as a result of forced breathing. As a tuberculous process becomes arrested, the atelectic areas show the presence of an increased amount of fibrous tissue; the alveoli are then permanently collapsed and râles can no longer be elicited.

The characteristic physical signs mentioned seem to be due to atelectasis rather than to the specific tuberculous infiltration.

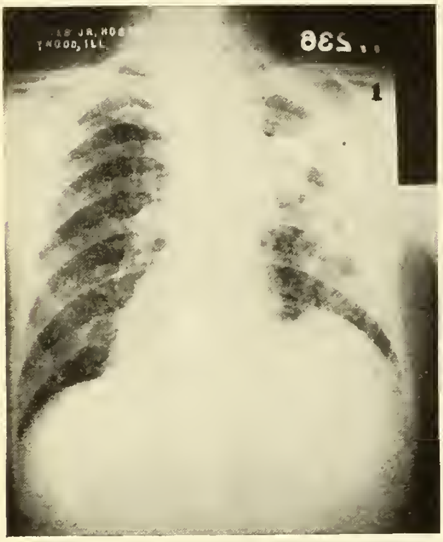
THE MECHANISM OF ATELECTASIS IN TUBERCULOSIS

In the newborn, the lungs completely fill the chest and the intrapleural pressure is equal to the atmospheric pressure. As development proceeds, the chest grows more rapidly than the heart and lungs, which causes the intrapleural pressure to become negative. Decrease of the lung volume in atelectasis or cicatrization further increases the negative pressure in the intrapleural space on the affected side. This causes a displacement of the mediastinum to the affected side. For the same reason, the diaphragm on the affected side is elevated by the abdominal pressure.

---

*Reprinted from Tuberculosis Abstract, a review for physicians, issued monthly by the National Tuberculosis Association, September, 1931, Vol. IV, No. 9.

Atmospheric pressure on the outside of the chest causes the crowding of the rigs, the deviation of the sternum, and the curvature of the spinal column. These abnormalities are more pronounced during inspiration because the intrapleural pressure is further lowered during this phase of inspiration since the collapsed lung cannot inflate sufficiently to fill the created space. During forced expiration, the conditions are reversed and the increased intrathoracic pressure is spent not in deflating the lungs but rather in displacing the mediastinum, which explains its pendulum movement.



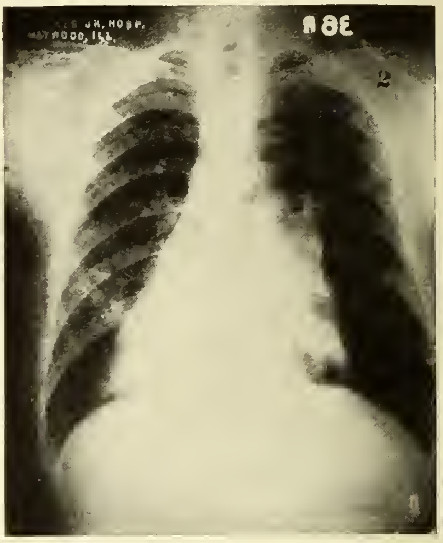
Tuberculosis of right lung. The right hemithorax and lung are contracted; the heart and trachea are displaced to the right and the diaphragm is elevated on this side.

As the absorption of air from the tissues is a rapid process, the visceral displacement is an early sign in tuberculosis, pneumonia, and in other diseases in which atelectasis occurs.—*Atelectasis in Pulmonary Tuberculosis, Ephraim Korol, Amer. Rev. of Tuberc., May, 1931.*

Treatment of Atelectasis in Pulmonary Tuberculosis

Lobar atelectasis or massive collapse has become a well recognized clinical condition. It is due to bronchial obstruction, complications of chronic pulmonary disease, tumors causing pressure. Glenn believes that lobar atelectasis, when occurring in pulmonary tuberculosis, is usually caused by obstruction of the bronchus to the lower lobe by pressure from a tuberculous lymph node or by contracting scar tissue. In his cases, atelectasis has developed slowly. He admits that none of his cases were bronchoscoped or came to autopsy and that, therefore, exact information concerning the etiological factors is not available.

Textbooks and medical literature give little information concerning the treatment of atelectasis as a complication of pulmonary tuberculosis. Aeration is sometimes restored without treatment. If the collapse has a sudden onset and the patient shows no tendency to hemorrhage, rolling the patient backward and forward with the involved side upward is sometimes effective.



Artificial pneumothorax induced without difficulty. The right hemithorax is normal in size. The viscera are in normal position.

The first patient with atelectasis treated by the author with artificial pneumothorax showed such marked improvement that the treatment was repeated in other cases thereafter. He reports seven cases of lobar atelectasis as a complication of pulmonary tuberculosis.

All seven cases were of the left lower lobe. Six cases were treated with artificial pneumothorax and all were benefited. In at least two cases, the prognosis was changed from unfavorable to favorable. One patient could not be given artificial pneumothorax because the pleural space was obliterated by adhesions. He concludes that atelectasis, when a complication of pulmonary tuberculosis, is not difficult to recognize if the likelihood of its being present is realized, and that artificial pneumothorax is the logical treatment for this condition.—*Massive Atelectasis in Pulmonary Tuberculosis and Its Treatment by Artificial Pneumothorax, E. E. Glenn, Amer. Rev. of Tuberc., May, 1931.*

THE EPITHELIOID CELL: R. S. Cunningham and Edna H. Tompkins (Amer. Rev. of Tuberc., 1931, XXIII, 71). Cunningham, Sabin, Sugiyama and Kindwall found that the characteristic cell of tuberculosis was considerably larger than the average monocyte, and often mononucleated. They also found great numbers of monocytes in association with epitheloid cells in tuberculous tissues. They observed all stages of transitions in type of staining from that characteristic of the monocyte to that characteristic of the epithelioid cell. They found that the Langhan's giant cells contained rosettes similar to those in the epithelioid cells. They formulated the concept that epithelioid cells develop from monocytes as a result of a tuberculous infection. Various investigators have since shown that stimuli other than tubercle bacilli can bring about the production of epithelioid cells, among them phosphatide fractions of tubercle bacilli, yellow phosphorous, nitrogen, oxygen, and carbon dioxide, or simply olive oil or mineral oil. The substances which stimulate the production of epithelioid cells and of Langhan's giant cells apparently act in such a way that the phagocytic of the monocytes becomes decreased, cellular division becomes abnormal, multinucleated forms appear, metabolism becomes disturbed and fatty degeneration takes place.

A. T. Laird, M.D.

PEDIATRICS

PREMATURE INFANTS—A STUDY OF 231 CASES OF PREMATURE INFANTS AT PHILADELPHIA LYING-IN HOSPITAL: W. H. Crawford, M.D., Philadelphia (Arch. of Ped., May, 1931, Vol. XLVIII, No. 5). Premature infants comprise all those born before the end of a full term intra-uterine pregnancy, and are therefore not fully developed. All those whose birth weight is less than five pounds are considered premature. Those with a birth weight between five and six pounds are considered immature, and those above six pounds are mature.

Hess says that a great number of premature infants die, not because their organs lack that degree of maturity necessary to proper functions, but because of early neglect, either through lack of adequate facilities or ignorance of exact methods of feeding and care.

Pediatric care of the normal premature resolves itself into:

1. Conserving body temperatures.
2. Providing suitable food.
3. Avoiding infections.

The cause of prematurity was determined in 91 cases, being: Syphilis 31, twins 26, toxemia 12, placenta prævia five, and others in lesser proportions. Average birth weight was four pounds, and gavage feeding was necessary in 17.4 per cent. Temperature was maintained in all cases by using an enclosed bed heated with electric lamps. Death occurred in 82 cases (35.5 per cent) due principally to: Prematurity, 50 per cent; syphilis, 23.2 per cent; pulmonary infection, atelectasis and intracranial hemorrhage, each 5 per cent.

R. N. Andrews, M.D.

DIE TUBERCULINPFLASTERPROBE—EINE VEREINFACHTE METHODE ZUR AUSFÜHRUNG DER PERKUTANEN TUBERKULINPROBE. N. Malmberg and B. Fromm (Acta Pediat., X:4,433, June, 1931). The authors describe a simple method of applying the tuberculin test percutaneously, which they have used in a series of 745 children in a Stockholm clinic. In the original method, a drop of tuberculin was applied to the skin over the sternum and carefully covered with a small square of adhesive plaster, a second square being applied to an adjacent area as control. After 48 hours the adhesive was removed. The appearance of papules, either distinct or confluent, was interpreted as a positive reaction. They later hit upon the idea of incorporating the tuberculin in the plaster in such a way that a drop was present in each square cm. of adhesive, a special control plaster also being made. In the first series of children, a Pirquet, Moro and tuberculin plaster test were applied simultaneously on different areas and all were read and recorded after 48 hours. In 92 per cent of the 745 cases, the results of the three tests were identical; in the remaining 8 per cent, indications were that the plaster and Moro tests were more sensitive than that of Pirquet. In a later series, the plaster test was applied to children who had been given a Mantoux test previously. A comparison of the results showed a high degree of accuracy in the percutaneous test.

The authors believe that the method described compares favorably with other standard methods, and that it has the double advantage of being simple in technic and of causing no discomfort to the patient. It was found that the tuberculin-plaster did not deteriorate when allowed to remain for a year in a tight container.

Louise G. Frary, M.D.

SINUSITIS IN CHILDREN: Henry A. Reisman, M.D., Jamaica, N. Y. (Arch. of Ped., May, 1931, Vol. XLVIII, No. 5). Sinusitis in children is fast becoming a problem of paramount importance because of its increasing prevalence, the difficulties encountered in diagnosis, the resistance of the sinusitis to treatment, and its many complications and sequelæ.

Accordi, in 1911, stated that it should be regarded as an established fact, when children suffer from frequent attacks of head colds, that some of the accessory sinuses are involved. Marriott states that more than half the children in the hospital wards are under treatment for some form of paranasal sinus infection, regardless of the diagnosis on admission. The presence of an overlooked or untreated sinusitis must undoubtedly be the cause of a great many disappointments following tonsillectomies. Sinusitis should be placed among the group of conditions to be considered when dealing with a child with fever of "unknown origin."

In sinusitis there will be a cough which is usually worse at night. The child is pale, fatigues easily, has frequent colds with evidence of nasal stoppage, and the throat shows evidence of a chronic infection with hypertrophy of the retropharyngeal glands, and one will usually find a postnasal discharge. The X-ray is a most valuable aid in the diagnosis of sinus infections.

The author has been using the high fat and protein and low carbohydrate diet which is being used in his chest clinic, for children suffering from sinusitis. The result of the treatment with the diet in some instances was striking, particularly from the standpoint of weight and general condition. The child should be placed in the hands of a competent laryngologist who has both time and patience for children. If there is any doubt as to whether there is pus in the antrum, it should be irrigated, either through the natural orifice or by way of antrotomy. The author believes, if the vaccine is autogenous, and properly given, the patient undoubtedly develops a greater resistance to nose and throat infections. Rest and prevention of over-fatigue is an important factor in the treatment.

R. N. Andrews, M.D.

BLOOD CHANGES IN ACUTE RHEUMATIC AFFECTIONS OF THE HEART DURING CHILDHOOD. Y. Åkerrén (Acta Pediat. X, 4:473-522, June, 1931). In introducing his study, the author presents two cases of acute polyarthritis in which there was apparently no heart involvement but which later developed a fatal endocarditis. He points out the importance of early diagnosis and the difficulties met with in interpreting physical signs and even X-ray findings in children. In an effort to find an objective test, he made a study of the blood of children suffering from acute heart disease following rheumatic joint affection. Subjects were chosen from the children's clinic of the University, Uppsala.

The most constant change in the blood was found to be an increased velocity in sedimentation of red blood cells. In no case where there were unquestionable clinical symptoms of acute heart involvement was this change absent. Increase in leucokyte and thrombocyte count was not found to be as constant or persistent. A comparison of temperature charts and sedimentation reaction graphs shows the latter to be a more sensitive indicator of the true cardiac condition. Sixteen cases are reported in detail. In one fatal case, there was no fever at all for a long period although the sedimentation increase remained high.

In therapy, bed rest was continued until after the sedimentation reaction had returned to normal. This was found to be fairly successful though fatal recurrences were observed twice, and the author feels that the period of rest should be longer.

Louise G. Frary, M.D.

RAW BASIC FEEDING IN ANOREXIA OF CHILDHOOD: I. Newton Kugelmass, M.D., and Emma L. Samuel, M.S., New York, (Arch of Ped., July, 1931, Vol. xlviii, No. 7). Anorexia is a chronic complaint, universal in apparently well children. The nutritional status of the child with chronic anorexia requires some immediate therapeutic procedure for the arrest of the progressive dystrophy. To await the return of a normal appetitie following the alleviation of the underlying condition causative of the anorexia admits of nutritional degradation of the child. The authors have therefore resorted to the use of a raw, base-forming dietary as an initial means to an end in conjunction with other necessary therapy. They have observed that the gastric offense—decreased motility, decreased hunger contraction, decreased hydrogen ion concentration, decreased emptying time—is common to all children with chronic anorexia irrespective of primary etiology.

The child with chronic anorexia has lost this psychological catalyst to initiate the hunger period, thus making the whole process of taking food very difficult. The psychological distortion in the child may either be hereditary, or acquired in the home, which is a veritable laboratory of psychic offense. The very structure of the child becomes transformed into the asthenic type as the result of unwholesome influence of its daily environment.

The authors have come to appreciate that the essential mechanism of digestion primarily depends on mechanical irritation induced by the food ingested. Loss of appetite in children is not a problem involving primarily inadequate gastric or duodenal juice or enzymes, but rather one of alimentary mechanics.

Offering nothing but raw basic feeding to carefully selected children with chronic anorexia is certainly productive of that type of mechanical irritation which a functionally atonic gastro-intestinal tract needs. The total effect is one of more complete emptying of the alimentary tract, thus favoring the development of more marked hunger contraction and its stimulation of the so-called hunger period.

Foods chosen for the anorexia diet are those in season which are universally eaten raw—the fruit, sound, ripe, well washed; the vegetable, crisp, clean and chilled. No foods are served between meals except fruit juice. Raw milk is served at each meal. No sugar or butter appears in the diet for the week, nor cooked food in any form.

The raw base-forming dietary is effective nutritional therapy for initiating the re-establishment of normal appetite, particularly when correlated with all other indicated therapy.

R. N. Andrews, M.D.

ROENTGENOLOGY

ROENTGENOLOGICAL APPEARANCE OF INTERLOBAR AND MEDIASTINAL ENCAPSULATED EFFUSION IN THE THORAX: Eugene Freedman, M.D., (Radiology, 1931, XVI, 14). Interlobar effusions occur more frequently after a pneumonia than from other causes. The shadow of such an effusion extends from the hilum to the lateral chest wall in a vertical of oblique direction and at different levels of the lung fields, according to which part of the fissure is involved. The size and form of the shadow is manifold depending on the amount of fluid and the compressibility of the neighboring lobes. Usually the lower lobe is compressed and in such cases the upper border of the shadow is sharp and the lower border somewhat less distinct in the postero-anterior view. Small exudates are often band or wedge-shaped and the larger ones are circular. In the lateral view the shadows often overlap the heart, are ribbon or wedge-shaped and have straight or circular but always sharply defined borders. The diaphragm remains in normal position and moves freely. When pneumonia, atelectasis or effusion into the entire pleural cavity are present the roentgenological examination is not very helpful. When gas or air escapes into the interlobar space the appearance may be that of a lung abscess. Marginal pneumonias (involving parts of lobes near the septa) localizing caseating pneumonias and bronchial carcinomata may simulate effusion. Lateral views will exclude lobar pneumonia. Marginal pneumonias and localzied caseated areas have usually only one sharp border. A marked anterior bulging in front of a pneumonia, the shadow of which is seen in lateral view suggests an effusion in front of the pneumonia. Lipiodal injections into the trachea visualize the defects and irregularities of the bronchial contour produced by carcinomata.

Mediastinal pleural effusions are, if serous, mostly tuberculous and if pleural, pneumococcal. The mediastinal pleura becomes involved from the tracheobronchial lymph nodes, the lungs, the pericardium, the thoracic wall or the mediastinum itself.

Anterior mediastinal effusions are represented by ribbon shaped shadows parallel to either the left or right silhouette and producing a double cardiac contour on the diseased side. The posterior mediastinal effusions produced either ribbon shaped shadows running parallel to the left or right borders of the vertebral column or triangular shadows in the cardiophrenic angles. In pericardial effusions the pulsations of the heart can be seen. Rotation of the patient helps to clear the diagnosis. When the lung about a bronchiectasis localized in the cardiophrenic sinus becomes surrounded with consolidated lung (pseudo-empyemic bronchiectasis), the diagnosis becomes very difficult unless lipiodal is used. Exploratory thoracocentesis would be of no value as purulent material might be obtained in any case. Mediastinal tumors, aortic aneurysms, or paravertebral abscesses may cause confusion. The tumors have lobulated contours, the aneurysm may show pulsations and the paravertebral abscess will be accompanied by narrowing of the intervertebral spaces or evidences of bone destruction. Seven cases of interlobar and two cases of mediastinal effusion are reported. These reports are accompanied by reproduction of X-ray films.

SURGERY

SPINAL ANESTHESIA BY LIMITED INDIVIDUALLY DOSED BELT-LIKE DISTRIBUTION: Prof. Kirschner, Tuebingen (Der Chirurg, July 15, 1931. Vol. 3, No. 14, Page 633). The new thought which Professor Kirschner develops in this article is that by limiting the amount of anesthetic used, and placing it in that bodily segment subject to operation, one can use less anesthetic and avoid some of the complications and dangers of the usual routine methods of spinal anesthesia.

By the new technic, which Professor Kirschner has himself applied in 160 cases, the dose is adapted to the requirement at the time it is given, by watching the distribution of the drug, and limiting it to the amount needed for the particular case.

The two directions in which spinal anesthesia may be counted as a failure, are (1) giving a dangerously larger dose than required, or (2) giving an insufficient dosage for the work in hand.

The author attempts to limit his anesthetic to that segment of the body which is under operation, without causing an anesthesia either above or below that particular segment. The principal features of the new technic are: The position of the patient, head down at an angle of 20 degrees; the injection of air into the subdural space, and the use of an anesthetic solution lighter than the specific gravity of the spinal fluid. He has worked out the solution and gives the formula and description of same, and he has also devised a syringe, which is double-barreled—one compartment for air, and the other compartment for the anesthetic solution. There is also described a spinal puncture needle, which is closed at the end and has a lateral opening.

This method of anesthesia has been used for lower as well as upper extremities, and for breast amputation. In abdominal work, in order to limit the amount of anesthetic put into the spinal canal, Professor Kirschner uses a regional block of the sympathetic nerves in the retroperitoneal space, after the abdomen is open. The drug which he uses is percain, because of its efficiency and duration of anesthesia produced.

His results in the use of this newer technic are as follows:

One can limit anesthesia to the distribution of a definite body segment with a full control of the caudal, as well as cranial extension of the area.

One avoids uncontrollable high distribution of the anesthetic, which might interfere with respiration or circulation.

One avoids the necessity of anesthetizing the lower end of the body.

Thus one has voluntary control over the upward and downward location of the anesthetic. In this way one gets a segmentary anesthesia with the minimum amount of anesthetic.

The dose is fitted to the individual case, by watching its immediate effects before a larger dose is used.

It differs from the lumbar anesthesia of Pitkin in that the lower end of the body is not necessarily anesthetized, since control of the site of the anesthetic is in a lower as well as in an upward direction.

The illustration of the physical conditions as they exist in the spinal column, with the heavy spinal fluid below, the floating fluid in the middle, with air on top, is well illustrated by diagram.

This new technic, worked out by a master surgeon, is of great practical interest in this day, when spinal anesthesia is being extensively used. As has been many times mentioned by those writing on this subject, anyone using spinal anesthesia, and especially a newer technic, should be absolutely versed in the physical, chemical, and physiological conditions under which he is working, before attempting the method.

To the experienced user of this form of anesthesia, any addition which either simplifies or makes safer this valuable form of anesthesia, is very welcome; and therefore the article by Professor Kirschner is a very valuable addition to this subject.

A. E. Sohmer, M.D.

BOOK REVIEWS

Books listed here become the property of the Ramsey and Hennepin County Medical libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

An Introduction to Gynecology. C. Jeff Miller, M.D., Professor of Gynecology, Tulane University School of Medicine, etc. 327 pages. Illus. Price: $5.00, cloth. St. Louis: C. V. Mosby Co., 1931.

Clinical Dietetics. Harry Gauss, M.S., M.D., F.A.C.P., Instructor in Medicine, University of Colorado, School of Medicine. 490 pages. Illus. Price: $8.00, cloth. St. Louis: C. V. Mosby Co., 1931.

American Physicians and Surgeons. Edited by James Clark Fifield. 1,737 pages. Price, $30.00. Minneapolis: The Midwest Company.

Modern Proctology. Marion C. Pruitt, M.D., Associate in Surgery, Emory University School of Medicine, etc. 404 pages. Illus. Price, $8.00. Saint Louis: C. V. Mosby Company.

Bedside Interpretation of Laboratory Findings. Michael G. Wohl, M.D., Associate Professor of Experimental Medicine, Temple University, etc. 321 pages. Illus. Price, $6.00. Saint Louis: C. V. Mosby Company.

Cutaneous X-ray and Radium Therapy. Henry H. Hazen, A.M., M.D., Professor of Dermatology, Medical Department of Georgetown University, etc. 166 pages. Illus. Price, $3.00. Saint Louis: C. V. Mosby Company.

COMMON CONTAGIOUS DISEASES. Philip M. Stimson. 353 pages. Illus. Price, $3.75. Lea & Febiger, 1931.

Here is a notable example of the kind of handbook that one often seeks but seldom finds. It is concise, explicit, complete, up-to-date, and devoid of inconsequential verbiage. The various contagious diseases are discussed adequately, and all of the most recent advances in that field are included. The general set-up of the book makes it attractive and easy to read.

Thomas Myers, M.D.

NEW AND NON-OFFICIAL REMEDIES, 1931, containing descriptions of the articles standing accepted by the Council on Pharmacy and Chemistry of the American Medical Association on Jan. 1, 1931. Cloth. Price, postpaid, $1.50. Pp. 481 + LVI. Chicago: American Medical Association, 1931.

This volume is the annual publication of the Council on Pharmacy and Chemistry of the American Medical Association giving the latest authentic information concerning those of the newer medicinal preparations found worthy of the consideration and use of the medical profession. Each year the Council scans the general articles under which the various preparations are classified and revises these to conform to the latest and best medical thought.

A glance at the preface shows that a number of preparations have been omitted because they conflict with the rules that govern acceptance, because their distributors did not present evidence to demonstrate their continued acceptability, or simply because the manufacturers have taken them off the market. Important revisions have been made in a number of the general articles and in the descriptions of various preparations. Among the new preparations that have been found by the Council during the past year to be eligible for admission to the book are: Amytal and Pulvules Sodium Amytal, 3 grains, barbituric acid derivatives for use preliminary to surgical anesthesia; Thio-Bismol, quinine bismuth iodide, sodium potassium bismuthyl tartrate, and Tartro-Quiniobine, bismuth compounds for use in the treatment of syphilis; Scillaren and Scillaren-B, preparations containing the squill glucosides; two new cod liver oil concentrates; Synephrine, a new vasoconstrictor, and synthetic thyroxine.

New and Non-official Remedies should be in the hands of all who prescribe drugs. The book contains information about the newer materia medica which cannot be found in any other publication.

WANTED—Salaried appointments for Class A Physicians in all branches of the medical profession. Let us put you in touch with the best man for your opening. Our nation-wide connections enable us to give superior service. Aznoe's National Physicians' Exchange, 30 North Michigan Ave., Chicago. Established 1896. Member The Chicago Association of Commerce.

WANTED—Scandinavian surgeon of thorough training and pleasing personality for Northwest clinic group. Possible permanent connection. Address D-142, care Minnesota Medicine.

WANTED—Young internist with X-ray experience for clinic group. Norwegian preferred. No investment required. Address D-141, care Minnesota Medicine.

DOCTOR'S OFFICES FOR RENT—Three good rooms over drug store in down town Minneapolis. Steam heat and hot water in winter. Wide stairway. Good location. Reasonable rent. Address D-144, care Minnesota Medicine.

CAPABLE X-RAY LABORATORY and PHYSIOTHERAPY TECHNICIAN wishes employment. Three and one-half years' experience clinical and general office duties. References. Address D-145, care Minnesota Medicine.

CAPABLE X-RAY and CLINICAL LABORATORY TECHNICIAN desires position. Available October first. Can do typing and general office work. Excellent references. Address D-146, care Minnesota Medicine.

Minnesota State Medical Association

Seventy-Eighth Annual Session

Minneapolis, Minnesota

PROCEEDINGS OF THE HOUSE OF DELEGATES FIRST MEETING—MONDAY EVENING, MAY 4, 1931

The meeting of the House of Delegates of the Minnesota State Medical Association, held in the Ball Room of the Nicollet Hotel, Minneapolis, Minnesota, convened at 7:00 o'clock P. M., Dr. L. Sogge, Windom, President of the Association, presiding.

President Sogge: The meeting will please come to order. The following have been appointed on the Credentials Committee: Dr. Wm. C. Carroll, St. Paul; Dr. John F. Fulton, St. Paul, and Dr. W. S. Broker, Battle Lake, which committee will report at this time.

Dr. Carroll: We have examined the credentials of the various delegates, and fifty-nine are present. The following delegates were present:

Blue Earth County—M. I. Howard, Mankato
Blue Earth Valley—J. L. Mills, Winnebago
Camp Release District—M. S. Nelson, Granite Falls
Central Minnesota—H. C. Cooney, Princeton
Chisago-Pine—F. F. Callahan, Pokegama
Clay-Becker—M. C. Bergheim, Hawley
Dodge County—F. D. Smith, Kasson
Freeborn County—W. L. Palmer, Albert Lea
Goodhue County—M. W. Smith, Red Wing
Hennepin County—W. A. Fansler, E. K. Green, J. A. Myers, E. A. Loomis, J. M. Hayes, A. S. Hamilton, Ivar Sivertsen, Chas. R. Drake, Ralph Knight, H. B. Hannah
Houston-Fillmore—Not represented
Kandiyohi-Swift—C. L. Scofield, Benson
Lyon-Lincoln—A. L. Vadheim, Tyler
McLeod County—Not represented
Meeker County—A. W. Robertson, Litchfield
Mower County—O. H. Hegge, Austin
Nicollet-LeSueur—Swan Ericson, Le Sueur
Olmsted County—A. W. Adson, W. F. Braasch, J. E. Crewe, E. S. Judd, L. W. Pollock, W. A. Plummer, A. H. Sanford
Park Region District—W. S. Broker, Battle Lake
Ramsey County—W. C. Carroll, J. F. Hammond, J. C. Hultkrans, Arthur H. Pedersen, E. M. Hammes, John Ryan
Redwood-Brown—Not represented
Red River Valley—H. M. Blegen, Warren; O. E. Locken, Crookston
Rice County—A. M. Hanson, Faribault
St. Louis County—F. H. Magney, Duluth; J. R. Manley, Duluth; B. S. Adams, Hibbing; C. L. Haney, Duluth
Scott-Carver County—F. C. Westerman, Montgomery
Southwestern Minnesota—E. W. Arnold, Adrian; S. A. Slater, Worthington
Stearns-Benton County—J. P. McDowell, St. Cloud
Steele County—A. B. Stewart, Owatonna
Upper Mississippi—C. E. Anderson, Brainerd; F. W. Van Valkenburg, Long Prairie
Wabasha County—D. S. Fleischhauer, Wabasha
Waseca County—B. I. Saliterman, Janesville
Washington County—E. S. Boleyn, Stillwater
Watonwan County—H. B. Grimes, Madelia
West Central Minnesota—B. R. Karn, Ortonville
Winona County—C. P. Robbins, Winona
Wright County—E. Klaveness, St. Paul

President Sogge: The minutes of the last session were printed in the October, 1930, number of Minnesota Medicine, and if there are no objections the minutes will be accepted without being read at this time. A motion was made and seconded that the reading of the minutes of the last meeting be dispensed with and the minutes accepted, which motion, being put to a vote, was carried.

We will now have the report of the Chairman of the Council. Dr. Workman.

MEETING OF THE COUNCIL

The Council of the Minnesota State Medical Association met at noon May 4, 1931. The following were present: Drs. L. Sogge, A. G. Schulze, M. S. Henderson, William A. Piper, H. M. Workman, J. S. Holbrook, F. J. Savage, N. O. Pearce, W. W. Will, O. J. Hagen, W. A. Coventry, George Earl, W. L. Burnap, W. A. Fansler, W. F. Braasch, C. B. Wright, E. A. Meyerding, O. E. Locken, J. R. Manley, H. M. Johnson, S. H. Boyer, F. E. Burch, W. C. Carroll, and H. M. Blegen.

The minutes of the last meeting of the Council held on February 7, were read and approved.

Dr. Locken, Chairman of the Special Committee to Study the Policies of the State Association, presented his report to the Council for its approval. A discussion followed and the report was referred to the House of Delegates.

At 2:00 P. M. the president called to order the meeting of the House of Delegates to abide with Chapter 5, Section I, of the By-laws. The meeting immediately adjourned.

The Council expressed its appreciation to Dr. Locken and the members of his committee for their work.

Mr. Van Riper of the Travel Guild, Incorporated, appeared before the Council submitting a proposition of a coöperative medical European tour to be conducted under the auspices of State Medical Journals. Motion made and seconded that the Council go on record as favoring the plan for Minnesota Medicine subject to the approval of the Editing and Publishing Committee.

The quarterly statement from MINNESOTA MEDICINE was read and approved.

A report of the budget expenditures to date was read.

A report of the Fiscal Agency Account was read and approved.

MOTION made by Dr. Coventry, seconded and carried, that the secretary be instructed to keep the budget expenditures as low as possible for the balance of the year.

MOTION made by Dr. Coventry, seconded and carried, that it be brought to the attention of the Editing and Publishing Committee that its report submitted this year was signed by Mr. Bruce and not by a member of the committee.

MOTION made by Dr. Coventry, seconded and carried, that the lunches for the members of the House of Delegates on Tuesday be paid for by the State Association.

Dr. Workman read a letter written by Dr. Hagen to the Red River Valley Medical Society.

MOTION made by Dr. Savage, seconded and carried, that Drs. C. B. Wright and J. T. Christison be recommended to the House of Delegates for reëlection as delegate and alternate to the American Medical Association for a period of two years beginning January 1, 1932.

A report of the membership was read by the Secretary. There are now 2,006 paid members in the Association.

A list of the affiliate applications to the American Medical Association was read; these were as follows:

S. S. Hall, Minneapolis
E. S. Strout, Minneapolis
E. H. Whitcomb, St. Paul
Chas. A. Van Slyke, St. Paul
Wm. F. Wilson, Lake City
L. K. Onsgard, Houston
Warren Wilson, Northfield

MOTION made by Dr. Pearce, seconded and carried, that the new plan for the certificates bearing the name of the County Society and its secretary be tried out for a year and that they be signed in the State office and sent directly to the membership.

A uniform fiscal year for the component societies was discussed and it was suggested that this matter be brought before the House of Delegates.

The question of redistricting Chisago-Pine and the Central Minnesota Medical Societies was referred to Drs. Savage and Coventry, councilors of the district.

Dr. Meyerding read several letters received by Dr. Johnson from various members congratulating him on the splendid work of the Committee on Public Policy and Legislation.

A question of a Service Medal for worthy members of the Association was laid on the table until next year.

MOTION made by Dr. Coventry, seconded and carried, that the Council endorse the request that the Basic Science Board be authorized to transfer some of its funds to the State Board of Medical Examiners for legal expenses incurred in the enforcement of the Basic Science Law.

A communication from the American Medical Association showed that many of the County Societies have not answered the questionnaire sent to them regarding their public health educational activities. The Councilors were urged to see that the secretaries in their districts answer this form.

MOTION made by Dr. Savage, seconded and carried, that the budget of the Historical Committee be increased to $750.00 as suggested in the report of this committee.

The following recommendation was submitted by the Committee on Public Policy and Legislation:

"TO THE COUNCIL OF THE STATE MEDICAL ASSOCIATION:

The Legislative Committee of the State Medical Association unanimously recommends, that in the publication in the register of the physicians licensed to practice in the State of Minnesota, some designation be made of those individuals who are members of the State Medical Association; provided this is not contrary to law.

H. M. JOHNSON
M. O. OPPEGAARD
C. B. WRIGHT
F. J. PLONDKE
N. G. MORTENSON.

Dr. Manley presented the report of the Reference Committee to the Council.

The meeting adjourned.

PRESIDENT SOGGE: You have heard the reading of the minutes of the meeting held by the Council. What do you wish to do with them?

A motion was made, seconded, put to a vote and carried, that the report be accepted.

PRESIDENT SOGGE: Next is the President's report.

I have no report to make, other than to say that I am very thankful to every member of the Association. It has been a wonderful pleasure to work with you because you do take hold, and when you have a membership that is willing to help and push, things come along very nicely. To expedite matters, because we have a good many things to consider, we thought we would follow this plan tonight: First, a report from the Reference Committee; then the Chairman of the committee will make remarks if he desires; then the subject will be open for discussion. We would like to hear on the floor of the House of Delegates anything anybody has to say. Don't be backward about speaking your opinion, because that is the only way we can learn how to carry out the work of the House of Delegates more efficiently. We have the Reference Committee, but that is simply to help us along—to go a little faster; it does not mean that we want to shut off any discussion. First in order is to head the Reference Committee on the Secretary's report.

REPORT OF THE SECRETARY

The past year has seen a steady increase in the routine work in the secretary's office. We regret to say that the committees, however, have not been as active as in the previous years—that is, their demands for services from the secretary's office have been smaller. Individual members, on the other hand, are learning, more and more, of the service that is available through the secretary's office. This accounts for the increase in the routine.

The demand upon the secretary's time, by the medical profession, has increased materially. During the past year the Secretary, personally, has been required to devote much more time than in the past to the needs of the various committees and local organizations.

NEWSPAPER SERVICE

The number of papers accepting this service has increased during the past year. We believe that its educational and general character has improved also. This is undoubtedly due to the fact that we are now writing our stories in our own office. The total number of papers accepting this service is 300. It is urged that the local physicians call these stories to the attention of their local papers, that they find out when the stories are published, and ask editors who do not publish them, why they are not doing so. All stories are censored by the Committee on Public Health Education.

COMMITTEES

During the past two or three years, our Committees have increased in size and number. It has been suggested that the committees are too large and unwieldy. The experience of the Secretary is that committee membership is always regarded as an honor. It might be advisable, however, to have an Executive Committee of three or five where the committees are large. The size has increased, due to the demand for geographical representation.

SERVICE TO STATE BOARD OF MEDICAL EXAMINERS

The new Medical Practice Act and Basic Science Laws have been so well enforced that a large portion of the members write to this office giving information of violations of these acts. This office has coöperated closely with the State Board of Medical Examiners and wishes to express its appreciation, particularly, of the services rendered by the Secretary of the Board.

COMMITTEE ON HOSPITAL AND MEDICAL EDUCATION

This Committee has been active in the past year in furthering post-graduate education amongst the membership. The Short Courses conducted by the Extension Division of the University of Minnesota have been successful as also were the new series of colloquium lectures. This service is of the highest value to our organization.

PAST PRESIDENTS

During 1930 the then President, S. H. Boyer of Duluth, Minnesota, visited practically every Medical Society in the State at a great expense and inconvenience to himself. Dr. Boyer has now placed himself as a competitor to his predecessor, Dr. C. B. Wright of Minneapolis. Both men were very active.

SEVENTY-SEVENTH ANNUAL MEETING AT DULUTH

This meeting was undoubtedly the most successful from a scientific, business, social, in fact from every aspect that your present Secretary has participated in. The local committees were very coöperative and very hospitable. The total attendance was 667, the largest ever held outside the Twin Cities.

HEADQUARTERS

The present arrangement for coöperation with the Minnesota Public Health Association continues to be of mutual advantage to both organizations. The publication *Everybody's Health,* is conducted on as high an ethical plane as possible.

HEALTH MEETINGS

Speakers have been sent out by the Public Health Education Committee to various parts of the state and to various organizations, such as the Parent-Teacher associations, Women's Federation, et cetera. Health meetings were also conducted, in conjunction with the Minnesota Public Health Association in various parts of the State. Dr. Morris Fishbein talked before three state conventions here last year. Dr. Fishbein addressed at least 20,000 persons during his two days' stay.

SECRETARIES CONFERENCE

The county and district Secretaries meeting was successful as usual. It therefore justifies its existence. Your secretary attended similar conferences in Iowa and Wisconsin.

PUBLIC RELATIONS

Your secretary was asked by the Secretary of the American Medical Association to present a paper last November at the Annual Conference of State Secretaries and Editors in Chicago. This paper was published in the January bulletin of the American Medical Association, and reprints have been sent to the members of our State Association. It should be a part of your Secretary's report to you today.

RADIO PROGRAM

The talks by Dr. W. A. O'Brien, University Hospital, Minneapolis, Minnesota, over Station WCCO are an unqualified success, not only in Minnesota but throughout the Northwest. They constitute one of the best investments that your organization has made.

EXPENSES

The expenses, other than the educational fund, have gradually increased due to the material growth, increased activities and the increase in the number of members taking advantage of the services offered. We have reached the limit of our expenditures. This is to be regretted as one of the most important phases of our educational work, that carried on by the Committee on Public Health Education, of which Dr. George Earl is Chairman, has not yet been thoroughly developed. It is now reaching the stage where more money should be expended. Greater activity is particularly necessary in our campaign for creating better Public Relations. Unless arrangements are made to increase the budget of this Committee the local societies will necessarily be obliged to increase their own activities as far as the public is concerned.

MALPRACTICE INSURANCE

During the past year our Insurance Company, which is the Aetna, made the following unsolicited reduction in their rates:

$10,000 to $30,000	$21.00

This is the basic rate and this form of insurance is written by this company for members of the State Association only. The former rate was $28.00.

The fact that the malpractice situation has improved and that reductions were therefore made possible, is undoubtedly due to our legislative program and condition of organization.

DAKOTA MEDICAL SOCIETY

There is none. The Council revoked the Dakota society charter because the physicians of Dakota County failed to comply with its provisions.

FISCAL YEAR OF THE COMPONENT MEDICAL SOCIETIES

At present there is no uniform date when the officers of the Component Medical Societies in Minnesota assume office. There are six dates set for the annual meetings of our thirty-six County Medical Societies. This irregularity makes it impossible for the state office to know who the officers of the component societies are. Frequently months elapse after a meeting before we are informed. It is suggested that the matter of a uniform date be considered. The following survey has been made in our office:

	ASSUMED OFFICE	DATE OF ELECTION
Blue Earth Valley	January	October
Central Minnesota District	January	January
Clay-Becker County	January	December
Dodge County	January	September
Freeborn County	January	December
Goodhue County	January	January
Kandiyohi-Swift County	January	December
Lyon-Lincoln County	January	October
McLeod County	January	January
Meeker County	January	December
Nicollet-Le Sueur County	January	December

Waseca County	December	December
Watonwan County	December	December

(No card received from Blue Earth County)

REGIONAL CONFERENCE

A meeting of the Northwest Regional Medical conference was held on February 8, 1931, at the St. Paul Hotel, St. Paul. Six states were represented, as follows: Iowa, North Dakota, Wisconsin, South Dakota, Nebraska, and Minnesota. A report of this meeting was published in the April issue of MINNESOTA MEDICINE.

LEGISLATION

We believe that during the past legislative session our Committee on Public Policy and Legislation has accomplished the greatest feat in its history as far as the welfare of the public and medical profession is concerned. The principle which declares that "every citizen has a right to select his own medical attendant" was sustained by the legislature. The set-back sustained in Minnesota by those interested in socialization will necessarily be long enduring.

AUXILIARY

Your auxiliary has made unusual advances during the past year and is becoming an active and valuable aid. The Secretary wishes to compliment the officers of the auxiliary for their activities. The profession, as a whole, should recognize and foster this very valuable service.

CONCLUSION

In conclusion it may be fairly stated that your association is making steadfast progress. It is today in the best condition of its history.

E. A. MEYERDING, *Secretary.*

DR. J. R. MANLEY (Duluth): You all have had a chance to study the Secretary's report. The Reference Committee has this to say: It is a very complete report and gives a comprehensive outline of the work of the Secretary's office. The Refereuce Committee moves its adoption.

PRESIDENT SOGGE: What do you wish to do with the report of the Secretary?

A motion was made, seconded and carried, that the report be accepted.

PRESIDENT SOGGE: Next is the report of the Treasurer.

TREASURER'S REPORT

RECEIPTS

Balance on hand Dec. 31, 1929		$ 1,293.47
Dues, placed to checking account	20,880.00	
Dues, placed to savings account	10,545.00	
Total		$31,425.00
Interest on savings funds	$ 439.46	
Interest on checking account	98.11	
Refund	27.00	
Total		$ 564.57
Bruce Publishing Co., 1929 profits		1,081.52
Bills payable		2,000.00
Total receipts		$36,364.56
Total disbursements		$29,020.57
Balance on hand Dec. 31, 1930		$ 7,343.99

DISBURSEMENTS

Public Health Education Committee	$ 5,899.06
Rent	300.00
Council	352.59
Miscellaneous	1,045.42
MINNESOTA MEDICINE	4,126.00
Bills payable $2,965; interest $35	3,000.00
Annual meeting	1,844.80
Secretaries' Conference	446.73
Furniture and Fixtures	22.61
Stenographers and clerks	1,654.05
Secretary's traveling expenses	603.13
Legal expenses	50.00
Treasurer's salary $100.00; expenses $3	103.00
Secretary's salary	3,600.00
Hospital and Medical Education Committee	215.10
State Health Relations Committee	3.29
Education Committee	5,117.03
Historical Committee	43.98
Printing	221.41
Auxiliary	57.37
Consultation Bureau	300.00
Refund in dues	15.00
Transferred to savings account	6,000.00
Total disbursements and transfers	$35,020.57
Minus transfer to savings account	$ 6,000.00
Total Disbursements	$29,020.57

STATEMENT OF CHECKING ACCOUNT

Balance on hand Dec. 31, 1929		$ 1,293.47
Dues deposited to this account		20,880.00
Interest on checking account		98.11
Interest refund		27.00
Bruce Publishing Co.		1,081.52
Transferred from savings fund—		
July 2,	$5,000.00	
Oct. 1	7,000.00	
Total		$12,000.00
Bills payable		2,000.00
Total receipts for checking account		$37,380.10
Total disbursements and transfers		35,020.57
Total in account on Dec. 31, 1930		$ 2,359.53
Outstanding checks Dec. 31, 1930:		
Nos. 396, 398, 403, 405, 408		655.56
Bank Balance on Dec. 31, 1930		$ 3,015.09

STATEMENT OF SAVINGS ACCOUNT

Balance on hand Dec. 31, 1929		None
Dues deposited to this account		$10,545.00
Interest April 1	$105.45	
July 1	166.50	
Oct. 1	118.16	
Dec. 31	49.35	
Total		439.46
Transferred from checking account		6,000.00
Total		$16,984.46
Transferred to checking account:		
July 2	$5,000.00	
Oct. 1	7,000.00	
Total		12,000,00
Balance in savings fund		4,984.46
Balance in checking fund		2,359.53
Total balance on hand Dec. 31, 1930		$ 7,343.99

The above balance of $7,343.99 on hand December 31, 1930, represents $2,000.00 Bills Payable which must be paid for immediately after the first of the year, and it represents $750.00 in 1931 dues collected before December 31, 1930. Deducting these sums we have a true balance left of $4,593.99.

A. G. Schulze, *Treasurer.*

Dr. Manley: The Reference Committee approves this report and moves its adoption.

Thereupon the report of the Treasurer was adopted.

President Sogge: Now comes the report of the Delegates to the American Medical Association.

Dr. W. F. Braasch (Rochester): We reported last year as the Duluth meeting came right after the meeting of the American Medical Association in Detroit. We have nothing further to report.

President Sogge: Dr. Wright will report on the Regional Conference.

Dr. C. B. Wright (Minneapolis): I think that has been very well covered in the April Minnesota Medicine, and there is also a little editorial in the May issue by Dr. Meyerding that covers the situation. But briefly, the Regional Conference was started by Dr. Braasch. We had the officers of Minnesota, Wisconsin, North and South Dakota to start with, and this last year Iowa, Nebraska and Montana were invited. The Montana delegates, however, did not get here. We had a very interesting meeting, and after this conference we realized that the problems which interest us interest all our neighbors. As you know, North Dakota has had a bad fight this last winter. They have been trying to pass a basic science law. Wisconsin is starting very active work in its association and has a remarkably active public health program. That organization is very progressive. We also had some very interesting men, like Mr. Wiprud, who is Secretary of the Medical Society of Milwaukee County. We also had the Managing Director of the Iowa Association, Mr. Blank, who discussed a plan for taking care of the Health of the Iowa poor. A rift in the lute, however, was the report that societies cannot practice medicine for profit. Another thing was the question of insurance by societies, but that was worked out by every one taking out insurance, and they have signed agreements with the counties in which they take care of their local problems and the county pays them a small amount for it. If any one would like to ask about the conference, I would be very glad to answer them. (No questions.)

A motion was, made, seconded and carried, that the report be accepted.

President Sogge: We will next take up the report of the Committee on Public Policy and Legislation, of which Dr. Herman Johnson is Chairman. I would like to say this about Dr. Herman Johnson—I like to compare him with Lindbergh. Lindbergh was the first to fly alone across the Atlantic Ocean, and I feel that Dr. Johnson was the first to "fly" in medicine in Minnesota. I feel that he is too big for Minnesota and we ought to have him in Washington, D. C., to protect our profession against socialized medicine. (Applause.)

Dr. H. M. Johnson (Dawson): Mr. President and members of the House of Delegates: I want to tell you that the result of the activities of our Association and the result of its success is due not to one single man or individual, but to the coöperation of every one in the Association and its officers. And that has been better this year than it has been in the past. I am not in a mood to speak very much tonight. I am sorry to tell you that I lost a man who was my partner for over thirty years. A week ago Sunday night he was taken with a stroke and never spoke again. It was Dr. A. A. Stemsrud. Many times I felt that I was abusing my associates by going away and staying away like I did and they worked hard and were not given any credit, while I was given lots of credit. Many times I said I had better stay home, and Dr. Stemsrud would always say, "You had better go, Herman, and do what little you can to put this Association on its feet, and when you get it going it can take care of itself, but now is the time when every one must do his duty." When I look at his death, a queer sensation creeps over me.

This year we had really believed there would not be much trouble. Of course, we feared the election. Those who worked and looked ahead and saw the returns in the primary knew pretty well what governor we were going to have. Governor Olson, I think, has kept his word with us, but we had to do all we could to be sure to get a good House and a good Senate. You know about these different cult bills that come up, and you know they always have to be followed. If you don't have a representative there looking after them, they will get you. I have always said we had as much power and money and influence as our opponents and would stay with them as long as it was necessary. There were many activities by certain interests in the fall campaign, and I thought another bill would come up which would try to set a price on the work done on industrial cases by medical men and also by the hospitals.

The thing you are interested in, I think, is what we took part in, and that was against the confirmation of Duxbury on the Compensation Board. The Legislative Committee and the Council have for two years been trying, through the Governor and every other way, to get him to live up to the law. We didn't change the law, but we helped to fix it so he was not confirmed, and therefore the next one that will be in, will be willing to live up to the law. It wasn't Duxbury, but it was the principle. He was dictating where a patient must go. The law is that the patient may choose his own doctor. He wrote letters to the patients telling them that unless they went to the doctor he specified, hospital and doctor bills would not be paid. That meant we had a lot of work to do. There is no question that men in the country, and I think men in the city, know that that class of patients was taken from the hands of the best doctors and sent to others. The insurance companies claimed that they could get it done cheaper elsewhere. I am sure the medical men did not charge them any unreasonable rate. All kinds if propaganda was used, and there is no question but what they tried to antagonize us in one way or another. But they did not succeed, and I am sure the medical profession stands closer together today than it ever did. And instead of weakening our position, it is now stronger than ever. While we had to fight against some of our friends, we never need to fear, because as long as we are right we will come out ahead. We are stronger than ever because we are standing together better and better, and it is not due to any one man but due to the coöperation of all of us. The councilors stood one hundred per cent solid, and the President was there. My trouble came onto me when I should have laid off, but at a time like that you can't lay off.

We had a conference with the Governor and told him what kind of a man we wanted on the Industrial Commission—a good, square man, one who was an able lawyer with a judicial temperament and a judicial mind, and that we didn't want a man who was especially favorable to the laboring man or the medical man or the insurance man. And we felt also that we didn't want any Farmer-Labor man. I am not particularly against the Farmer-Labor party, but the law prescribes that the members of this Board shall be of different parties. The medical men tell me Mr. Gallagher of Waseca is as good a man as could be picked, and even the Republicans, those who fought for Duxbury so strongly and were very much interested in the insurance companies, told us he was all right, that it was a good appointment and they were well satisfied. Duxbury's policies were the beginning of state medicine. Maybe pretty soon half of the people will be protected by state insurance, and if the patients had to go where they were directed it would be a sad state of affairs.

We never, apparently, will get through with the quacks, but I think we have broken their backs more and more every year, because as the law is enforced more of them go to jail; but if we want to protect ourselves we absolutely have to fight every year.

Gentlemen, I want to thank you all and thank the ommittee. By standing together in the future like we have done in the past we can protect our interests, and our interest is our profession. I only wish our Naional Association was as active in looking after its nterests as we are in this state; this state has become known throughout the country as one of the most aggressive states

PRESIDENT SOGGE: It is wonderful for the Legislave Committee to be able to report one hundred per cent from a legislative session. I doubt if any other state ould do the same. I think the Legislative Committee ught to be congratulated and thanked for its efforts, nd with them Dr. Workman who spent a great deal f time in St. Paul looking after our affairs. Is there ny discussion on this report?

DR. A. H. PEDERSEN (St. Paul): In the first place, would like to know why a written report was not endered. It seems to me the chairman should render written report to the State Society. In the second lace, while it is shown that $5,000.00 was spent last ear, I understand there was $7,000.00 actually spent, nd I cannot understand why $7,000.00 was spent durg a non-legislative year. Another thing is, have we eally killed contract medicine? The University conacts to take care of students at a special rate. At entral High School in St. Paul we have free X-ray nd Mantoux tests. Isn't that state medicine? Have e closed all the portals to state medicine? I feel the societies which claim to be friendly to medicine are really antagonistic, because they have not said anything about paying for the examinations. I would like to hear why that money was spent.

DR. C. P. ROBBINS (Winona): I had the pleasure of being with the Legislative Committee last year. If any member would like to have information regarding how money was spent on legislative work, Dr. Johnson has had the accounts audited, and if any doctor is interested he can go to the Auditing Committee and get the information.

PRESIDENT SOGGE: Dr. Johnson, did you hear the question that was asked?

DR. JOHNSON: The Council has those matters in charge, and I think they have taken care of that part. Legislation goes on most all the time, and if you know anything about how things are done in the Legislature by other concerns you will know something about it. There was lots of work done. As to why it was not a written report, I think you have the report now. There was a report sent out, that is, a letter was sent out summarizing the activities during the session, but if you want another one, we will gladly furnish it.

PRESIDENT SOGGE: Where did you get the information that $7,000.00 was spent?

DR. PEDERSEN: From Dr. A. G. Schulze.

DR. A. G. SCHULZE (St. Paul): I think you are mistaken on that. $5,000.00 was the total.

PRESIDENT SOGGE: Are there any further questions?

DR. F. F. CALLAHAN (Pokegama): I would like to say something about the Mantoux tests in these cases of tuberculosis. I think if you are going to do anything to eradicate tuberculosis we must start at the root. If the practitioners can get the pupils in and do the work themselves, if they can convince the people that it is necessary, that will take care of the whole business. We have conducted some of these tests in the schools at Pine City. We were astounded at the results we found. We couldn't possibly get those people to come in as private cases. But when we found anything wrong with the patients, we referred them back to their private physicians for treatment. I know it is wholesale, but it is about the only way we can find the condition.

DR. WRIGHT: There seems to be some misunderstanding about this particular thing, and as I have been on the Legislative Committee for three sessions, I would like to say a word about it. I don't think the Mantoux tests in St. Paul schools have anything to do with this controversy. Possibly this gentleman does not know some of the things about this business that I do. When Dr. Johnson was asked to take the chairmanship of this committee, he specified two things only —One, that he should be given a budget, and that the Auditing Committee should audit it. I know the average professional man knows nothing at all about practical legislation. When I became a member of this committee I knew nothing about it, but I have learned considerable about this subject since. I know that you can't make an itemized report of any legislative activity and retain any influence whatever in the legislature. I doubt if any doctor here keeps an itemized report of his own personal expenditures. The way I feel about it is this: I don't know what you think about our efforts in the last six years. That is a matter for you to decide. But please decide that we are going to do some legislative work—and we are going to do it effectively—or we are not going to do it at all, because you are not going to do any effective work if you tie the hands of your committee member and make him give a report of every dollar he spends. If there is any intelligent criticism of what we have accomplished, let's hear it. Let's hear something constructive about the legislative program. I have been working with Dr. Johnson for six years and I never found him doing anything that was not on the square. When he returned from the hospital, men in the legislature and men who have fought him—put their arms around him and said, "Herman, we are glad to see you back, let's get together and work for the next campaign," that means something.

Dr. H. M. Workman (Tracy): I have been Chairman of the Finance Committee, and am Chairman of the Council. At Dr. Johnson's request I have attended all the meetings and stayed in St. Paul when I should have been taking care of my own business. But I know where every dollar has gone. I can't do more than that for you. I have done it honestly. If any man wants to question my honesty he can do it. The money was spent honestly, and we got results. If anybody thinks we didn't get results I would like to have him say so.

Dr. Robbins: We carried on the work at our own traveling and hotel expense and we never took a penny from the Legislative fund.

Dr. S. H. Boyer (Duluth): It is my opinion that anybody who asks such questions as have been asked here has never served on any Legislative body. For several years I have heard these little nagging and creeping complaints and questions as to what has been done with this five cents or this two cent stamp. They seem to be bothered about what we are going to do with a nickel or a dime. You can't get any place with that stuff. You have to spend your money if you want to live. What did you have before you spent any money in this state, Doctor? Did you have any influence?

Dr. Pedersen: No.

Dr. Boyer: Are you proud of what we have done, or not?

Dr. Pedersen: Absolutely.

Dr. Boyer: It leads me to suspect that some of you question the integrity of our Council and Dr. Herman Johnson. I assure you that every dollar has been spent with wisdom and intelligence. It is my opinion that if twice the money had been spent that what we got would have been cheap. Today the profession in Minnesota sweeps on with a grandeur that is not surpassed by any other state in the Union. It covers everything we can reach to protect the state against quackery and state medicine. We can't reach all these things at once, but we hope to succeed in getting to them. You have mixed our legislative work with University relations work. That is a matter that should be considered entirely separate and apart from what we are considering tonight.

Dr. A. B. Stewart (Owatonna): I am on no committee, but when I read in the report what Dr. Johnson's committee has accomplished, instead of criticizing it I move that we give a rising vote of confidence for the work they have done.

President Sogge: I would first like to know how many of the delegates here don't believe that they got value received for what was spent for the legislative work. When we get value received, what are we kicking about? I would like to hear from Dr. Slater on the Mantoux tests.

Dr. S. A. Slater (Worthington): This Mantoux test is something new. It has to be put on a firm foundation, and at the present time it is only in the experimental state. We know that the Mantoux test is a means of finding children who are infected with tuberculosis. We further know that the majority of children in whom we find the infection come from homes in which the infection exists. It is highly important that the Medical Association coöperate. When a child reacts to the test he is sent back to his family physician and he may look for the source of the infection. I think this is a very valuable means of finding the source of infection and eradicating tuberculosis. I believe the doctors are learning something about tuberculosis which will be of benefit to themselves as well as to their patients. And if the medical profession does not do what it should to eradicate tuberculosis, other forces will step in and do their part. With the medical profession conducting these tests I think the best results can be obtained without any danger of it becoming state medicine.

Dr. W. S. Broker (Battle Lake): During the past year we have conducted about 2,500 Mantoux tests on school children. It is almost impossible to get the children to go to a physician to get the test. In order to cover any ground at all it has to be done in what has been called a wholesale fashion. It has to be done in groups. I think for each child it is a very valuable experience. I think, far from being a detriment to the profession, it is going to be an advantage. The children are going to appreciate medical care and are going to have more work done and more attention paid to them than if it had not been done at all.

Secretary Meyerding: It happens that in Ramsey County there is an organization known as the Ramsey County Public Health Association. The Minnesota Public Health Association has little to say about Hennepin, Ramsey and St. Louis Counties. But in Ramsey County we are conducting what is known as the Mantoux test. It is done by Dr. Geer. I think the question Dr. Pedersen presented is a matter for the Ramsey County Medical Society to take up rather than one for this Association. We all know that state medicine is one of our problems. It is just around the corner in the United States. Canada now has it. We just have to wait until some state legislature will pass a law creating state medicine. I might explain to you something that might be considered along the same line. That is heart disease. For several years there has been a National association dealing with heart work. A few years ago a representative of that group came to me and asked if we would take it over. I did not care to consider it, but knew that if we did not, somebody else would; so we finally took it over. We have a heart committee in the State Medical Association, and the time is coming when the public will demand that we do something along the line like this tuberculin testing, social diseases, and so forth. If you don't recognize these movements and take a part and coöperate and assume leadership, somebody else will and you are going to be left in the background where you were all these years in the past. We have attempted to coöperate with the medical profession.

I think the most ideal example of what I am telling you about was done in Owatonna. A meeting was held there of the county medical society and the public health association. The family physician took care of those who were infected. Everybody who has a positive Mantoux reaction is referred to his physician for treatment, and I think it is a benefit to the medical profession as well as to the patient.

Dr. Wright: We have gone away from the question, our Legislative program. I think this is the vital thing that you are interested in, because you are spending your money on it. The thing I want is to hear you men discuss the legislative program. Possibly you don't know what was concerned in that Duxbury fight to start with. Two years ago they introduced a maximum fee bill. At that time three or four members of our committee tried to get in touch with Mr. Duxbury to discuss this bill with him. He said, "I have nothing to do with the bill, I am only on the Industrial Commission." We went before the Committee and were able to convince them that the bill would hurt the patient. In other words, if you put the maximum fee too low it will deprive them of all the care they need, and if you put the maximum fee too high it makes the insurance too high. So Senator MacKenzie, the sponsor of the bill, withdrew it. This year they tried to introduce a bill which would give the Industrial Commission the right to set the maximum fee; and when we found out the facts of the case, Mr. Duxbury admitted to Mr. Brist that he drew the bill himself. I will admit that I would not have had the nerve to go against Mr. Duxbury, because I knew what was behind him. I want to tell you that Mr. Fesler told me that if it were not for the demonstration of the power of the Medical Association in preventing the endorsement or confirmation of Mr. Duxbury, it would eventually have resulted in the loss of thousands and possibly millions of dollars to the hospitals and profession of this state. That is one of the things this committee has accomplished.

I would like to have some constructive and intelligent criticism about what has been done by this committee. But I think the mere discussion of how people spent a few dollars here or there is entirely outside the question.

Dr. F. H. Magney (Duluth): I am not on any of the committees, and personally I don't care to know where any of the $5,000.00 has gone. I appreciate the efforts of Dr. Johnson and this committee, but I have even failed to write to my legislators in compliance with the request of Dr. Johnson.

Dr. B. S. Adams (Hibbing): I have known Herman Johnson ever since I went to school, and I know he is not only efficient but honest. I want to make a motion that we give Dr. Johnson a rising vote of thanks for the splendid work he has done.

A rising vote of thanks was then extended to Dr. Johnson.

Dr. Johnson: I wish to thank you gentlemen. I beg no favors. I respect and admire the interest and enthusiasm you have shown, and the gentleman who has so much to complain about I want to tell him that if he knew more about what he talked he would not talk that way. I wish he was doing it himself.

President Sogge: The next report is the report of the Committee on Public Health Education.

REPORT OF THE PUBLIC HEALTH EDUCATION COMMITTEE

The Committee has continued its past policies of reaching the profession and placing before them problems that exist in their relations with the public. At the same time a consistent contact has been kept up with the public itself. The Chairman of this Committee is also a member of the Committee on State Health Relations and the Public Health Nursing Committee. These memberships are for the purpose of correlating the activities of the committees mentioned.

EXPENDITURES

We are presenting a financial statement that shows the various expenditures under definite heads. It will be noted that there are several expenditures that are not primarily the function of this Committee, but were made upon the request of the Council. Our total Annual Budget Expenditure is a financial statement of the activities of our Committee, plus other financial outlays voted by the Council.

FINANCIAL REPORT

1930 Analysis of the Public Health Education Expenditures

Mr. Brist	$ 479.09
News Service	1,300.90
Meetings—Public Health, Med. Economics, County Society, Officers Conferences, Public Health Nurses, etc.	355.62
Sundries, Petty Cash, Telephone, Telegrams	19.58
Stenographer	1,310.00
Misc. Postage and Printed Matter	78.81
Speakers Library Material	36.95
Radio	528.36
Speakers—State Annual Meeting at Duluth, Health Tours, etc.	767.68
Legislature—Hygeia and Everybody's Health	314.50
A. M. A. Delegates Expense	168.80
Diphtheria Prevention Campaign	538.77
Total	$5,899.06

F. MANLEY BRIST:

Mr. Brist gave talks upon the activities of the Minnesota State Board of Medical Examiners and the operation of the new Medical Practice Act and Basic Science Laws. These talks were given to both medical and lay groups for the purpose of emphasizing the importance of the enforcement of medical laws. The following groups were addressed by Mr. Brist during the past year:

Nicollet—LeSueur County Society.
Secretaries Conference.
Mankato, Blue Earth County.
Stillwater, Lions Club.
Hennepin County Auxiliary.
Colloquium Course at Winona.
Wadena.
Freeborn County.
Mower County.
Iowa State Medical Association.
St. Cloud, Stearns-Benton County.
Blue Earth Valley.
Willmar-Kandiyohi-Swift County.
Wabasha County.
Olivia.
Houston-Fillmore County Society.

NEWS SERVICE

The weekly newspaper service has continued to grow and improve. Thanks in a large measure to the facilities offered by the Minnesota Public Health Association, who have made it possible for us to engage expert service at a minimum expenditure. The number of papers are gradually increasing, until we have now 300. A sub-committee is appointed to censor the newspaper stories.

MEETINGS

Public Health—Medical Economics—County Society—Officers' Conferences—Public Health Nurses

Traveling expenses of various members of the Association were paid for attending meetings at which they spoke. These meetings consisted of Public Health meetings, Medical Economic meetings of the various county societies, and all Public Health Nurse groups.

STENOGRAPHER

The Committee has always paid the salary from its budget of one of the employees at the State Office. While this employee is only giving part time to the Committee, yet the entire time of this person is being charged. Commencing with 1931 a pro-rata arrangement has been made whereby the salary will be distributed in a different manner.

SPEAKER'S LIBRARY MATERIAL

Suitable material was purchased and distributed to the members of the Committee and for filing in our lay speaker's Library.

RADIO

This series of talks are undoubtedly the most popular health talks in this section of the radio world. The Committee believes in Dr. O'Brien's talks from both the scientific and organization standpoint and that they are well worth the cost.

SPEAKERS—ANNUAL MEETING, HEALTH TOURS, ETC.

In this are included the fees necessary to be paid to lay speakers at various health meetings which we participated in and also the honorarium and expenses for two of the speakers at the last annual meeting in Duluth amounting to $206.23.

Rev. Wm. C. Sainsbury of Fargo assisted at the following places:

Waseca County Public Health.
St. Olaf College.
Kandiyohi County P. T. A.
Lyon Lincoln Medical Society.
Women's Federated Clubs, Olivia.
Comstock Federated Clubs.
Glenwood Kiwanis, P. T. A. and High School.
Detroit Lakes P. T. A., High School.
Crookston Seal Sale Institute.
Luverne Lecture at High School.
Alexandria P. T. A. meeting.

LEGISLATURE—HYGEIA AND EVERYBODY'S HEALTH

We have again the past year sent Hygeia and Everybody's Health magazines to the Legislature of Minnesota.

A. M. A. DELEGATES EXPENSE

The Council ordered that the expenses of the delegates to the American Medical Association be drawn from our budget.

DIPHTHERIA PREVENTION CAMPAIGN

As our part of the Diphtheria campaign, which the Minnesota State Board of Health, Minnesota Public Health Association and the Committee on Hospitals and Medical Education are sponsoring, we expended a considerable amount for posters that were distributed to the schools and other public places.

CONCLUSION

While we aim to instruct the public as regards scientific medicine and have them realize that on the whole their best interest lies in the hands of the members of the State Association, a large part of our work is within the profession and might be considered organization work.

George Earl, *Chairman.*

Dr. Manley: The Reference Committee commends the very valuable work of the Public Health Education Committee, and recommends that the activities of this committee be continued. We recommend the adoption of this report.

Dr. George Earl (St. Paul):

In the four years in which we have been allowed a budget, we expended in 1927, $2,033.77 out of an allowance of $5,000.00; in 1928 we expended $3,944.26 out of an allowance of $7,000.00; in 1929 we expended $4,304.15 out of an allowance of $7,000.00, and in 1930 we expended $5,899.06 out of an allowance of $6,000.00; or during the four years of our existence we have expended only a part of what we were authorized.

Our reasons for this economy were: First, that the work was new and we desired to approach the subject cautiously. In the second place, by coöperating with the Minnesota Public Health Association, we were able to undertake the program with greater economy than probably any other State Association. Third, the work undertaken has been only in direct response to requests from the officers, council, county societies and members of the Association.

Such expenses as that of Mr. Brist in connection with the explanation of the operation and enforcement of the New Basic Science Law and the New Medical Practice Act to the Medical Profession; the Radio Committee's expense; the coöperation with the Legislative Committee by sending Hygeia and Everybody's Health to all the members of the Legislature; the A. M. A. delegates' expense; the foreign speakers to the Annual State Meeting in Duluth; and the stenographic and office expenditures in connection with a great many of the other Committees and activities have been charged to our budget.

A review of the present State Organization would show that we deal with questions of public health contact through the following Committees:

The Committee on State Health Relations.
The Radio Committee.
The Committee on Contract Practice.
The Committee on Medico-Legal Affairs.
The Committee on University Relations.
The Heart Committee.
The Committee on Schools for Laboratory Technicians.
The Committee on Public Health Education.
The Committee on Hospitals and Medical Education.

The Legislative and other Committees also have dealings with the public.

Medical leadership should be encouraged in the County as regards Public Health Association, Red Cross, Editorial and Legislature coöperation and other public contacts. The major portion of our committee's time and if you will look at the budget of the four years and especially the first years, the major portion of our committee's budget has been expended on encouraging such local leadership.

Anyone that has had any experience in this matter will realize the difficulty of securing local medical leadership. A few places have it and have put on excellent programs; this because of their own native ability. Where we find that such native ability does not exist it is just as difficult to promote it as it is in any other phase of life. From promoting county and local medical leadership has come the demand for a demonstration by the State Society in the form of radio talks, or newspaper service and of help on Public Health Meetings as the opening wedge of contact toward further establishing the relations that your Committee suggests. In the State of Minnesota there are millions of dollars spent annually effecting the question of Public Health Education. We have Corey, McFadden, and other newspaper service; Christian Science, patent medicine propaganda, League of Medical Freedom and Anti-Vivisection Leagues; then all of the cults; further, lay organizations for tuberculosis, cancer and heart; and all of the forces of state medicine and state institutions, privately endowed institutions and all the private practice activities of our association members.

The problem for the Minnesota State Medical Association to determine is, first, shall we as an organization take any part in directing public health activities and in influencing public health opinion by any other method than that of our scientific achievements. Undoubtedly the scientific practice is the contribution that should take the vast majority of our energy, but if some public health education work is not undertaken will there be other forces without our help sufficient to counteract the aggressive attacks of those whom we believe to be in error on public health problems.

Our Committee has always felt that the best possible public contact depends on the scientific ability, public health attitude and willingness to undertake its individual share of advancing the cause of health by each one of the two thousand members of the Association in his daily medical practice and contacts of life. Of necessity some type of organization is advisable to help in some small measure with planning and demonstration.

Dr. E. Klaveness (St. Paul): Would it not be possible next year to save the expense of $479.00 paid to Mr. Brist?

Dr. Earl: I don't know if I am as well qualified to answer that question as the Council is. We are paying $2.00 per year to the Board in whose employ Mr. Brist is, and they are a Board appointed by the State of Minnesota through the Governor. This Board would be subject to criticism if Mr. Brist did any work for us on time for which he is paid by them. Fortunately, Mr. Brist is a wonderful speaker before luncheon clubs, etc. We are able to secure this rather brilliant, able attorney for $400.00 a year, and in my mind we should thank the State Board of Medical Examiners for letting us share Mr. Brist at this nominal expense. Does that answer your question?

Dr. E. Klaveness: Yes.

Upon motion regularly made and seconded the report was accepted.

President Sogge: The next report is that of the Editing and Publishing Committee.

REPORT OF EDITING AND PUBLISHING COMMITTEE

It again becomes my privilege to submit a report on the publication of your journal, Minnesota Medicine, for the year. The period covered in the report is the calendar year of 1930.

The twelve numbers of the journal included in Volume XIII contained a total of 1290 pages, or an average of 107.5 pages for each issue, the largest number of pages that has ever been printed in any one year. Of this total, 938 pages were devoted to reading matter and 352 to the advertising section, making an average of 78.2 pages of reading matter and 29.3 pages in the advertising section for each issue. The total number of illustrations was 323. This is also the largest number of illustrations ever printed in the journal in one year. Had all this editorial material been supplied to the readers in book form, it would have been a volume of 1,200 pages with more than 300 illustrations.

The total number of articles published during the year was 131, 16 of which were case reports. Other case reports and discussions of interest to the medical profession were published in the Proceedings of the Minnesota Academy of Medicine and the Minneapolis Surgical Society.

Several changes have been made during the year in the personnel of the staff contributing to the progress section. This section, under the direction of Dr. Lewis M. Daniel of Minneapolis, has continued to be a definite service to readers of the journal. A section entitled Tuberculosis Abstracts has been added under the heading of Medicine. These Abstracts are direct reprints of the monthly bulletin of that name published by the National Tuberculosis Association. Another recent addition to the journal is the publication of the Proceedings of the Minneapolis Clinical Club.

The circulation of MINNESOTA MEDICINE for the year 1930 is reported as follows:

Members (paid)	2,053
Members (delinquent)	148
Non-member subscriptions	105
Miscellaneous copies distributed single copy sales, exchanges, complimentary, advertising, etc.	369
Surplus on file	125
Total	2,800

The following report of receipts and disbursements from the period January 1, 1930, through December 31, 1930, was submitted to the secretary of the Association in January, 1931:

CASH RECEIPTS

Display advertising	$ 8,780.17	
Illustrations	98.82	
Member subscriptions	4,106.00	
Non-member subscriptions	310.48	
Advertising dividend	462.04	
Total Cash Receipts		$13,757.51

CASH DISBURSEMENTS

Journal expense		$14,023.37	
Discounts allowed:			
Advertising	$1,205.01		
Subscriptions	22.25	1,227.26	
Total Cash Disbursements			$15,250.63
Cash deficit for the period			1,493.12

It is much to our regret that the publication shows a deficit for the period. This is the first year since MINNESOTA MEDICINE was established more than thirteen years ago, that a deficit has been shown. This was due to two causes, the most important perhaps being the general business depression, general throughout the country, which had a serious effect upon our advertising volume. The other cause was the increased cost of printing due to the fact that nearly 100 pages more were printed than during any previous year, and that a larger number of copies were printed and distributed than for any previous similar period. The editors also used a larger number of illustrations in the journal than for any other year, and this cost alone amounted to in the neighborhood of $500 more than for any previous year.

Effective January 1 the advertising rates in the journal were advanced ten per cent. This advance applies to practically all the advertising contracts now in course of execution and to any new business which may be signed during the year. We are hopeful that this small increase in the advertising rates will serve to enlarge our volume, in conjunction with a greater volume of new business which we hope to obtain with improved conditions, to make a much more favorable showing for 1931 than was made for the previous year. Already, for the first quarter of 1931, we show an increase of approximately 15 per cent in volume of display advertising over the corresponding period for last year.

If the moderate improvement which has been shown in business conditions continues for the year, we believe that the amount of display advertising executed in the journal will be more than sufficient to prevent a deficit for this year. It should be borne in mind, however, that the sale of advertising is largely contingent upon a maintenance of the improvement in business conditions. The experience of MINNESOTA MEDICINE during 1930 is not unlike that of practically every other publication of a similar character in the whole country last year. As a matter of fact, daily newspapers and large magazines similar to the Saturday Evening Post and the Ladies' Home Journal and others of that type, showed an enormous loss in lineage. It is a condition over which we, of course, have no control, but you may rest assured that we are putting forth every possible effort to maintain and increase our volume for this year.

Respectfully submitted,
J. M. ARMSTRONG, *Secretary.*

DR. MANLEY: The Reference Committee moves the adoption of this report.

Upon motion regularly made and seconded the report was adopted.

PRESIDENT SOGGE: The report of the Radio Committee.

REPORT OF THE RADIO COMMITTEE

One hundred and sixty-four radio programs were broadcast under the direction of the Radio Committee from April 3, 1928, to May 1, 1931. With the exception of two programs from Station KSTP, all have been sent from Station WCCO. A complete list of the programs up to June 1, 1930 (117), may be found in MINNESOTA MEDICINE, Proceedings of Sixty-second Annual Meeting, xiii, 750:751, October 1930. From June 1, 1930, to May 1, 1931, forty-seven additional programs have been broadcast:

Subjects: (1) Cardiac Neurosis; (2) Minnesota Department of Health; (3) Pyelitis in Young Girls; (4) Pituitary Gland; (5) Vacation Time; (6) Growth in Childhood; (7) Cause of Hernia; (8) Facial Neuralgia; (9) Common Foot Disorders; (10) Poison Ivy; (11) Knock Knees and Bow Legs; (12) Cause of Fever; (13) Cancer of the Stomach; (14) Bowel Obstruction; (15) Trench Mouth; (16) Cause of Flatulence; (17) Acne; (18) Finish the Job; (19) Cancer of the Rectum; (20) Father of Medicine; (21) Food Fads; (22) Finger Infections; (23) Poliomyelitis; (24) Treatment of Cataract; (25) Carcinoma of the Lip and Mouth; (26) Psoriasis; (27) Gallstones; (28) Mental Hygiene; (29) Christmas Seal; (30) Cancer of the Skin; (31) Carbon Monoxide Poisoning; (32) Peanut Bronchitis; (33) Cause of the Common Cold; (34) Cancer of the Breast; (35) Humidity in the Home; (36) Control of Diphtheria; (37) Treatment of Constipation; (38) Cancer of the Uterus; (39) The Rheumatic Child; (40) Treatment of Insomnia; (41) Cause of Meningitis; (42) Cancer of the Bladder; (43) Health Education; (Third Anniversary) (44) High Blood Pressure; (45) Health in the Home; (46) Nervous Exhaustion; (47) Cancer of the Kidney.

All have been sent from Station WCCO, Wednesday mornings at 11:15 a. m. The change from the earlier time (10:15 a. m.) was made during the winter months because of conflicting stock market reports. Station WCCO still continues to voluntarily ask our aid in censorship and has been most coöperative in this and other regards. Good publicity has been received during the past year from the papers and the station. In addition, special notices of the programs are being sent to various journals and publications which reach the medical nursing professions.

Abstracts appear every month under the title "Health from the Air," in Everybody's Health. The audience is apparently growing, and mail is still received from Minnesota, North and South Dakota, Iowa, Wisconsin, and Northern Michigan. Mail from interested listeners is becoming heavier as time goes on. In addition, the Committee has learned, directly and indirectly (from personal contacts), of the large number of people who are regular listeners and are pleased with the service. The attitude from the beginning has been to offer a message which was not too complicated for the ordinary layman to understand, and which contained something of practical interest for him. Interest in health grows with understanding. The air is polluted more than ever with quackery. The attitude of Station WCCO in this respect is commendable. In addition to furnishing us with the time and facilities for the program without charge, they have voluntarily excluded from their programs, anything which was not in accord with the type of service the medical association was attempting to render through health education. There is much work to be done along these lines with the other stations not only in Minnesota but through the country (chain broadcasts). The value of health education through sustained effort and constant repetition of certain ideas (although only a very small number of talks have been repeated) is very evident. We are now entering our fourth year of broadcasting (3rd Anniversary, April 3, 1931) and believe that the future has even greater possibilities in store. The Committee urges that the programs be continued, and expresses its appreciation for the many favorable comments received on the service rendered.

We are making a survey of the broadcasting stations in Minnesota as to the type of advertising that is going over the air—whether it is ethical or not, etc. We regret that our data is not complete for this report.

L. R. Critchfield, *Chairman.*

Dr. Manley: The Reference Committee believes that the work of this committee and that of Dr. O'Brien is of the utmost value. It particularly commends the committee for attempting the survey of stations broadcasting in Minnesota as to the type of medical advertising on the air—whether it is ethical or not. We move the adoption of this report.

The motion to accept the report was seconded and carried.

President Sogge: The report of the Historical Committee.

REPORT OF THE HISTORICAL COMMITTEE

At the banquet of the state meeting of the Minnesota State Medical Association in June, 1927, Dr. C. H. Mayo called attention to the advisability of preparing a medical history while we have the older members still with us. The report of the Council meeting of October 12, 1927, contains a motion by Dr. Wattam that a historical committee be appointed by Dr. Wright to gather data concerning the history of the Minnesota State Medical Association. A committee of seven was subsequently appointed and has since been at work gathering material for a history and preparing it for publication.

Two formal reports have since been made to the Council and House of Delegates and one to the society, outlining the headings under which we have planned to write the history. In 1929, we stated at some length our troubles in securing necessary facts, in arranging them in readable form and the long labor of corroborating data from sources often untrustworthy.

Material for our history has come in slowly. Though a number of the chapters are now practically ready for printing, there are others on which we have made no progress whatever and it now seems to us that we shall be obliged to find someone else to write certain chapters. Under these circumstances, parts of our history will be much delayed.

Under similar conditions, some of the states have brought out their history in volumes appearing at such times as the accumulation of material has permitted. Your committee recommends similar action in respect to the Minnesota history and we believe we now have on hand material sufficient for Volume No. 1. Of course, the contents should be such that each chapter will bear some natural relation, as chronological, to other chapters, though we will also have to be governed somewhat by the actual material available.

We believe we could have ready for the first volume something concerning the real pioneers, such as certain medical men who were associated with the early fur companies; Dr. Williamson, the medical missionary; Major Purcell, who came here as the medical officer to the troops to build Fort Snelling, and John Marsh, who was his pupil. The history of the Minnesota State Medical Association and of the Ramsey and of the Hennepin County Medical Societies is already typed. We also have a manuscript of a few pages, prepared by a Dr. Fairchild, who was here in very early days and who wrote a most interesting article concerning pioneer conditions. Dr. Clark, of the Soldiers Home, had an article years ago on the physicians of the St. Croix Valley and we believe we could get ready something concerning the Winona group which was a very distinguished lot of men and perhaps the Red Wing men and the Duluth group and something concerning the early physicians of the Minnesota River Valley.

This would give a group of articles, all dealing with very early times, and would be sufficient to make one volume of about the size that we agreed upon as satisfactory when we adopted in a tentative way such a volume as the Michigan State Society has put out, a copy of which is on exhibition. Though we have entered on no formal arrangement with anyone, we have had the advice of Mr. Bruce, publisher of MINNESOTA MEDICINE, and we expect to prepare a volume about seven by ten inches and containing about nine hundred pages. The history of the Michigan State Medical Society seems to us very desirable in size, form and general appearance.

Michigan has 3,476 members in its State Society and they published 1,100 copies of a two volume history or 2,200 books. Minnesota has 2,227 members in its State Association and Mr. Bruce suggested that we publish 1,000 copies, bind 500 copies and use the remainder when needed. If we prepare one volume of 900 pages, it would cost about $2,900 to $3,200 with index and plates. If we prepare two volumes, and we think this will be necessary, of about 900 pages each, it will cost us something like $5,000 to $6,000 for the two volumes. This would include the index and a reasonable number of plates.

The eventual cost to the State Association is a matter of much importance. Illinois, with a State Society membership of 7,361, at $5.00 per volume, sold 500 copies of the first volume, or a percentage of practically seven. Michigan, with a membership of 3,476, at $5.00 per volume, also sold 500 copies, or a percentage of fourteen. Nebraska, with an Association membership of 1,207, at $15.00 per copy, sold to 25 per cent of the members. North Dakota with a State Association membership of 391, at $3.50 per volume, sold copies to 55 per cent of its members. These figures show a very wide range in the percentage of copies sold to members in the different states.

We advise that our history be published in two volumes of 1000 copies each, each volume containing 900 pages, and that Volume No. 1 be put into type as soon as is reasonably possible. We also advise that 500 copies of Volume No. 1 be bound as soon as printed and be sold at $5.00 per copy or volume. We further advise that there be a preliminary canvass of the entire Association membership so that we may have some idea in advance of publication of the number of books needed. Naturally, the result of this canvass may make some change in our plans.

Up to date, practically all work on the history, including even the typing has been done gratuitously by individual members of the Association, but we feel that in the course of the ensuing year, the time will arrive when certain expenses must be borne by the Association. Someone should conduct a preliminary canvass of the medical men of the state. Secretarial assistance will be necessary in the proof-reading and the preparation of the index besides certain typing which should not be left to the Committee's personal secretaries. We have not meant to imply that there has been any shortage in money supplied us in the past. On the contrary, we have at all times been alloted a much larger sum than we have ever used. It has merely been a case that in the many more or less minor situations that have arisen, it was not convenient to ask for outside assistance.

We have no definite idea as to just what these special situations will call for, but we estimate an index at something like $175.00 and the bill for rewriting copy preliminary to publication will be at least $250.00. As far as we can judge, $750.00 is a fair sum to add for these special situations and this is in addition to the cost of final publication as referred to previously.

If the Association authorizes the publication of Volume 1 at this time, we will make an attempt to have it ready for the 1932 meeting, but previous experience has made us cautious in giving definite promises.

ARTHUR S. HAMILTON, *Chairman.*

DR. MANLEY: The Reference Committee realizes the value of this important work and recommends that the question of the time of publication, expenditure of money, and so forth, be referred the Council for action.

DR. A. S. HAMILTON (Minneapolis): Mr. Chairman and Members of the House of Delegates: We have already presented a formal report on this subject and explained our views as well as we could. Anyone who has looked over the report will observe a very great difference in the sale of the copies. In North Dakota they sold 55 per cent of the members of the society, and in Illinois about 7 per cent. There should be a careful investigation over the state to see how many are willing to purchase a publication of this sort. If anyone has any questions about the matter, I would be glad to answer them if I can.

DR. ROBBINS: I move that the report be adopted.

The motion was regularly seconded, put to a vote and carried.

PRESIDENT SOGGE: Next is the report of the Necrologist.

NECROLOGIST'S REPORT

May, 1930, May, 1931

MEMBERS OF MINNESOTA STATE MEDICAL ASSOCIATION

ANDREW E. ANDERSON, Minneapolis. Born 1859. Colorado University. Died, Dec. 11, 1930. Aged 71.

Charles Riggs Ball, St. Paul. Born 1867. University of Minnesota, 1894. Died, Dec. 19, 1930. Aged 63.

Bernhard Stanton Bohling, Sandstone, Minn. Born 1887. Northwestern University, 1912. Died, Dec. 20, 1930. Aged 43.

Dwight F. Brooks, St. Paul. Born 1849. Long Island College Hospital, 1876. Died, January 21, 1930. Aged 81.

Theodore Bratrud, Warren. Born 1873. University of Minnesota, 1898. Died, Dec. 6, 1930. Aged 57.

Alfred Erwin Comstock, St. Paul. Born 1872. Hahnemann Medical College of Chicago, 1899. Died, July 24, 1930. Aged 58.

Charles Frederick Disen, Minneapolis. Born 1861. Rush Medical College, Chicago, 1886. Died, August 6, 1930. Aged 69.

Frederic A. Dunsmoor, Minneapolis. Born 1853. Bellevue University. Died, Dec. 16, 1930. Aged 77.

Brainerd Pease Flinn, Redwood Falls. Born 1892. Rush Medical College, Chicago, 1918. Died, March 3, 1931. Aged 39.

Luther Lewellyn Gibbon, Lowry. Born 1876. University of Minnesota, 1897. Died, May 24, 1930. Aged 54.

Alfred Benjamin Hart, Jr., Owatonna. Born 1902. St. Louis University School of Medicine, 1925. Died, Jan. 4, 1931. Aged 29.

Walter B. Holmes, Ada. Born 1866. University of Minnesota, 1894. Died, Oct. 27, 1930. Aged 64.

August Elof Johnson, Minneapolis. Born 1869. Hamline University, Minneapolis, 1906. Died, Oct. 19, 1930. Aged 61.

William A. Jones, Minneapolis. Born 1859. University of the City of New York, 1881. Died, Jan. 15, 1931. Aged 71.

John A. Lyng, Minneapolis. Born 1864. University of Minnesota, 1890. Died, Sept. 27, 1930. Aged 66.

O. S. Neseth, Kenyon. Born 1886. University of Illinois, 1917. Died, April 23, 1931. Aged 45.

J. P. O'Connor, St. Paul. Born 1869. Minneapolis Physician's and Surgeon's College, 1900. Died, March 2, 1931. Aged 62.

William Phelps Robertson, Litchfield. Born 1887. Detroit College of Medicine and Surgery, 1912. Died, Oct. 21, 1930. Aged 43.

Andrew Soderlind, Minneapolis. Born 1862. University of Minnesota College of Medicine and Surgery, 1890. Died, March 22, 1931. Aged 69.

A. A. Stemsrud, Dawson. Born 1872. University of Minnesota, 1901. Died, April 27, 1931. Aged 59.

Fred A. Swartwood, Waseca. Born 1860. Medical College, Ann Arbor, Michigan, 1886. Died, Nov. 12, 1930. Aged 70.

PHYSICIANS NOT MEMBERS OF STATE ASSOCIATION AT THE TIME OF DEATH

William A. Chamberlin, Waseca. Born 1856. Rush Medical College, Chicago, 1882. Died, Sept. 27, 1930. Aged 74.

Alexander Augustus Cirkler, Minneapolis. Born 1865. University of Berlin, 1893. Died, Dec. 30, 1930. Aged 65.

John Charles Drexler, Brandon, Minn. Born 1851. Died, Jan. 22, 1931. Aged 79.

William Henry Hallowell, Minneapolis. Born 1853. University of Pennsylvania School of Medicine, 1880. Died, Dec. 14, 1930. Aged 77.

Olaf E. Krogstad, Minneapolis. Born 1862. University of Vermont College of Medicine, Burlington, 1893. Died, May 14, 1930. Aged 68.

George Allen Love, Preston. Born 1851. Bennett College of Eclectic Medicine and Surgery, Chicago, 1874. Died, Dec. 4, 1930. Aged 79.

Charles M. Long, Osakis. Born 1849. Rush Medical College, Chicago, 1878. Died, Aug. 3, 1930. Aged 81.

Jacob Wright Magelssen, Rushford. Born 1844. Rush Medical College, Chicago, 1866. Died, Jan. 9, 1931. Aged 87.

Hertz Nathaniel Meleck, Minneapolis. Born 1880. Medical Department, Hamline University, 1903. Died, March 27, 1931. Aged 51.

S. P. Meredith, Mankato. Born 1852. Hahnemann Medical College and Hospital, Chicago, 1882. Died, Sept. 30, 1930. Aged 78.

Walter Arthur Monnich, Minneapolis. Born 1884. Baltimore Medical College, 1910. Died, Aug. 28, 1930. Aged 46.

Louis Leypoldt Moench, Waterville. Born 1876. Eclectic Medical Institute, 1903. Died, June 2, 1930. Aged 54.

Charles I. Remington, Walnut Grove. Born 1860. College of Physicians and Surgeons, Keokuk, Iowa, 1879. Died, July 3, 1930. Aged 70.

John Frederick Russ, Blue Earth. Born 1866. University of Iowa, 1893. Died, Aug. 13, 1930. Aged 64.

M. L. Stiffler, St. Paul. Born 1887. University of Colorado, 1913. Died, Sept. 7, 1930. Aged 43.

Louis Leonard Ten Broeck, Minneapolis. Born 1876. Rush Medical College, Chicago, 1907. Aged 54.

Frank L. Wilcox, Walker, Minn. Born 1877. Rush Medical College, Chicago, 1900. Died, Aug. 29, 1930. Aged 53.

Ulysses G. Williams, Minneapolis. Born 1865. University of Minnesota, College of Medicine and Surgery, 1889. Died, Jan. 13, 1931. Aged 66.

Oesten K. Winberg, Lake Park. Born 1864. University of Minnesota, College of Medicine and Surgery, 1892. Died, Dec. 27, 1930. Aged 66.

Christopher J. Woolway, Duluth, Minn. Born 1854. McGill University Faculty of Medicine, Montreal, 1875. Died, Oct. 28, 1930. Aged 76.

Dr. Olga S. Hansen (Minneapolis): It seems but right and fitting that in the midst of this manifestation of the things that are of immediate interest to us we stop for a few moments to pay tribute to the members who have died during the past year. The names of twenty-one members have come to the attention of the committee. You know the names and you will recognize those of personal friends and others who have done very much for the cause of medicine in this state. "For them life's duration was measured by deeds done, and not by years lived. Nothing is here for tears, nothing to wail or knock the breast; no weakness, no contempt, dispraise or blame, nothing but well and fair and what may quiet us in a death so noble."—(Milton.)

President Sogge: As a mark of respect for those who have passed on, let us stand a moment in silence.

The audience rose and stood in silence.

The Report of the Committee on Hospitals and Medical Education.

REPORT OF THE COMMITTEE ON HOSPITALS AND MEDICAL EDUCATION

The new committee chairman is presenting herewith his first report of the Committee on Hospitals and Medical Education. The wholehearted coöperation of Mr. Richard Price of the Extension Division of the University of Minnesota has made possible the following list of lectures during the past year. In addition, there is appended a report from Dr. W. A. O'Brien which itemizes the work of the Consultation Bureau.

In the near future a new booklet containing titles and a short abstract of each lecture will be sent to the secretaries and correspondents of every county society.

We hope to enlarge the scope of this committee during the coming year. We solicit the constructive criticism of every member of the state society, hoping that this will make it possible for us to improve our lectures so that they will become more popular.

REPORT OF EXTENSION COURSES

June 1, 1930, to May 31, 1931

Below is a summary of the medical short courses conducted by the General Extension Division since May, 1930:

HAWLEY

July 12—Dr. Owen H. Wangensteen—The Diagnosis and Treatment of Acute Intestinal Obstruction.

Cost—$33.00

FERGUS FALLS

Oct. 1—Dr. G. B. Eusterman, Rochester—Gastro-Intestinal Disease.

Oct. 15—Dr. Moses Barron, Minneapolis—Hypertension.

Nov. 12—Dr. G. B. Doyle, Rochester—Neurological Diagnostic Methods.

Nov. 19—Dr. H. G. Irvine, Minneapolis—Skin and Syphilis.

Nov. 26—Dr. Wallace Cole, St. Paul—Orthopedic Surgery.

Dec. 3—Dr. J. M. Hayes, Minneapolis—Treatment of Varicose Veins and Ulcers.

Cost—$75.00. Average attendance—18.

HIBBING

Sept. 4—Dr. Emil Geist, Minneapolis—Personal Experiences with the Bohler Treatment of Fractures.

Sept. 18—Dr. F. W. Spicer, Duluth—Heart Diseases.

Sept. 25—Dr. W. A. Coventry, Duluth—Abnormal Menstruation, Especially Painful Menstruation, and Abortion.

Oct. 2—Dr. W. F. Braasch, Rochester—Hematuria.

Oct. 16—Dr. E. L. Tuohy, Duluth—Non-Tuberculous Chronic Lung Conditions.

Oct. 23—Dr. A. S. Hamilton, Minneapolis—Examination of Cases for Testifying in Court, Especially Compensation Cases.

Oct. 30—Dr. S. H. Boyer, Duluth—Status of State Medicine.

Nov. 6—Dr. Leo Rigler, Minneapolis—Diagnosis of Bone Diseases (Not Tumors), Especially Adolescent.

Cost—$185.00. Average attendance—25.

LITTLE FALLS

Oct. 1—Dr. W. E. Patterson, Minneapolis—Diseases of the Nose, Throat and Accessory Sinuses.

Oct. 8.—Dr. Moses Barron, Minneapolis—Diabetes.

Oct. 15—Dr. E. M. Hammes, St. Paul—Problems in Diagnosis between Functional and Organic Nervous Diseases.

Oct. 29—Dr. E. S. Platou, Minneapolis—Contagious Disease Symposium.

Nov. 5—Dr. H. E. Michelson, Minneapolis—Dermatological Clinic (Lantern).

Nov. 12—Dr. Gilbert J. Thomas, Minneapolis—Prostatic Disease.

Nov. 19—Dr. C. W. Waldron, Minneapolis—Oral Surgery.

Dec. 3—Dr. H. M. N. Wynne, Minneapolis—Gynecology.

Cost—$120.00.

MARSHALL

Sept. 30—Dr. Rood Taylor, Minneapolis—Disease and Disturbance of Digestion in Infancy and Childhood.

Oct. 14—Dr. P. W. Giessler, Minneapolis—General Orthopedics.

Oct. 28.—Dr. J. S. Lundy, Rochester—Local, Spinal, and Sacral Anesthesia, etc.

Nov. 4—Dr. W. H. Goeckerman, Rochester—The Relationship of Dermatosis to General Medical Problems.

Nov. 18—Dr. H. C. Habein, Rochester—General Medicine.

Cost—$115.00. Average attendance—30.

OLIVIA

Sept. 8—Dr. H. B. Zimmerman, St. Paul—Acute Abdomen.

Sept. 22—Dr. L. A. Brunsting, Rochester—Itching Skin.

Sept. 29—Dr. E. M. Hammes, St. Paul—Problems in Psychiatry.

Oct. 6—Dr. H. M. N. Wynne, Minneapolis—Gynecology.

Oct. 13—Dr. W. A. Plummer, Rochester—Goiter.

Oct. 27—Dr. S. M. White, Minneapolis—Heart.

Nov. 3—Dr. A. F. Bratrud, Minneapolis—Injection of Varicose Veins.

Nov. 10—Dr. Norman M. Keith, Rochester—Dehydration.

Nov. 24—Dr. W. W. Lewis, St. Paul—Middle Ear.

Dec. 1.—Dr. C. W. Waldron, Minneapolis—Oral Diseases.

Cost—$130.00. Average attendance—19.

WINONA

Jan. 14—Dr. F. A. Willius, Rochester—Some Principles Underlying the Treatment of Heart Failure.

Jan. 28—Dr. Norman M. Keith, Rochester—Diagnosis and Treatment of Nephritis.

Feb. 11—Dr. W. A. Fansler, Minneapolis—Diseases of the Rectum.

Feb. 25—Dr. W. A. Plummer, Rochester—Diseases of the Thyroid.
Mar. 11—Dr. J. F. Weir, Rochester—Jaundice.
Mar. 25—Dr. B. F. Davis, Duluth—Traumatic Infections.
Apr. 8—Dr. W. H. Goeckerman, Rochester—Dermatosis.
Cost—$92.00.

MANKATO

Dec. 4—Dr. Moses Barron, Minneapolis—Cardiac Decompensation and Treatment.
Dec. 11—Dr. G. B. Eusterman, Rochester—Unfamiliar Lesions of the Stomach, with Differential Diagnosis.
Dec. 18—Dr. Edward Cathcart, Rochester—Infections of the Lower Urinary Tract.
Jan. 8—Dr. John F. Madden, St. Paul—Dermatology.
Jan. 15—Dr. F. J. Hirschboeck, Duluth—Borderline between Internal Medicine and Psychiatry.
Cost—$96.00. Average attendance—15.

DULUTH

Colloquium Series, Winter of 1931

Correspondent—Dr. F. J. Hirshboeck, Duluth, Minnesota.

Dec. 15—Dr. W. A. O'Brien—Pathology.
Dec. 29—Drs. S. H. Boyer, L. Sogge, N. O. Pearce, E. A. Meyerding—Meeting under the Auspices of the State Medical Association.
Jan. 12—Drs. J. A. Myers, Walter H. Ude, A. T. Laird—Meeting under the Auspices of the Minnesota Public Health Association.
Jan. 26—Meeting under the Auspices of the State Board of Health.
Feb. 9—Dr. Irvine McQuarrie, University Medical School—The Nature and Treatment of Various Convulsive Disorders of Infancy and Childhood.
Feb. 23—Dr. T. L. Birnberg, St. Paul—My Impressions of Russia, Particularly from the Medical Aspect.
Mar. 9—Dr. F. H. K. Schaaf, Minneapolis—Recent Advances in Therapeutics.
Mar. 23—Dr. Frank Whitemore, St. Paul—Injuries to the Skull, Vertebræ and Peripheral Nerves.
Cost—$80.00.

REPORT OF THE CONSULTATION BUREAU

January 1, 1930, to January 1, 1931

NUMBER OF INQUIRIES RECEIVED ACCORDING TO MONTH

January	7
February	5
March	3
April	20
May	22
June	12
July	5
August	8
September	10
October	10
November	3
December	5
Total	110

TYPES OF INQUIRIES RECEIVED

Case reports requesting: General Information; Diagnosis; Prognosis; Treatment of Diseases; Reading of Dental Films, and Reading of X-ray Pictures.

Other letters for general information requesting: Information Regarding Schools; Books; Patent Medicine; Blood Test to Prove Paternity; Drugs; Analysis of Food Products; Teeth, and Immunization. Medicolegal Matters; Apparatus and Appliances; Locum Tenens and Locations and Placement in State Institutions.

Many of the case reports were followed by further inquiry.

Gilbert J. Thomas, *Chairman.*

Dr. Manley: This committee has submitted a very full report, and they particularly ask for suggestions from the delegates and members as to how they can improve their work. The Reference Committee commends this report and recommends its adoption.

Upon motion regularly made and seconded the report was accepted.

President Sogge: The report of the Heart Committee.

REPORT OF HEART COMMITTEE

In answer to your note of February 17 requesting a report of the Heart Committee of which I happen to be acting chairman, I regret to say that after conferring with Dr. Hirschboeck, we have no report of any definite progress having been made. The plans outlined to you in the report by Dr. Hirschboeck last year are still in the immature stage and have as yet not been crystallized. We still have the idea of having, at some time, a series of articles on cardiac subjects appear regularly in the Minnesota Medicine. A number of local societies are devoting a little time at each meeting for a discussion of cardiac problems and a few speakers on cardiac subjects have been requested to appear before local or groups of local societies.

There has been no recent meeting of the Heart Committee to my knowledge but the ideas that were discussed and accepted at the last meeting still retain their value and when put into execution, will undoubtedly be of definite benefit.

Respectfully yours,
H. E. Richardson,
Acting Chairman.

Dr. Manley: The Heart Committee has no definite report. They are working slowly. We recommend the adoption of this report.

Dr. H. E. Richardson (St. Paul): The only point I would like to emphasize is that the Heart Committee would welcome any coöperation from the secretaries of the various component societies so that we could work out a series of short talks—in other words the development of a speakers bureau.

Upon motion regularly made and seconded the report was adopted.

President Sogge: Next is the report of the Committee on Medico-Legal Affairs.

REPORT OF COMMITTEE ON MEDICO-LEGAL AFFAIRS

The following is a report of the Committee on Medico-Legal affairs, for the current year:

1. An investigation of the conduct of certain attorneys in handling a malpractice suit, was requested by a member of this Association, with a view to possible disbarment proceedings as a result of unprofessional and unethical conduct. A quiet investigation of this has been carried on, and at this time is not fully complete, but it is the belief of this committee, at this time, that while the ethics of the legal profession were definitely violated by these attorneys, there is not sufficient foundation for disbarment proceedings. Opinions have been sought and obtained from attorneys in the State Bar Association, and they concur in this belief. The matter has not yet been disposed of, but in all probability this investigation will not bring the results desired by the member of this Association.

2. This Committee has studied the file submitted by secretary's office, in December, 1930, concerning the decision of the Supreme Court in a malpractice suit against certain members of this Association, which apparently nullified the Statute of Limitations. The case has been very thoroughly studied by the Chairman of this Committee, but in view of the present legislative situation, it has been deemed unwise to take active steps at this time. The file is being held for such action in the future as it may seem best to take.

3. No further definite action has been possible concerning the enactment of legislation regulating expert testimony in criminal cases. This matter was referred to in our report of last year, and we feel, at this time, just as we did then—that it is a desirable objective. We realize, also, that it requires a constitutional amendment, and that the legal profession, properly should lead in this measure. We feel that this objective should be borne in mind and we shall endeavor to work toward it, to the best of our ability.

Other than the above, no matters have come to the attention of this Committee.

W. H. Hengstler, *Chairman.*

Dr. Manley: We move that the report of this committee be accepted.

The motion was seconded and carried.

President Sogge: Now the report of the Committee on Schools for Laboratory Technicians.

REPORT OF THE COMMITTEE ON SCHOOLS FOR LABORATORY TECHNICIANS

In our last annual report made at the Duluth meeting, we suggested several things.

The first was that the Legislative Committee of the Minnesota State Medical Association take steps to enact laws controlling these Schools of Medical Technology. The time is not quite ripe when this should be done.

Another recommendation we made was that Dr. Kano Ikeda, a member of the American Society of Clinical Pathologists, be made a member of our Committee. This society has formulated a standard for laboratory technicians and is conducting a registry of technicians. They are now at work on formulating a standard for Schools of Medical Technology, and that is why we deemed it advantageous to have Dr. Ikeda a member of our Committee.

Since making our last report, two members of the Minnesota State Medical Association, were asked to discontinue their association with a certain school of Medical Technology, by the Executive Committee of their County Society. They did so in a most courteous manner.

Beyond this your Committee on Schools for Laboratory Technicians has not done much work because we are waiting for the American Society of Clinical Pathologists to finish their standardization for Schools of Medical Technology and then we will have something definite to talk about, and a standard to be followed, and the Schools of Medical Technology will either qualify by coming up to this standard or fail to do so.

A. G. Schulze, *Chairman.*

Dr. Manley: The Reference Committee commends the action of this committee in persuading two members of the State Association to discontinue their affiliation with a certain school of medical technology. We move the adoption of the report.

Upon motion regularly made and seconded the report was adopted.

President Sogge: The report of the Committee on Public Health Nursing.
